<b>1</b>	<b>Input-Output Reference</b>	<b>25</b>
1.1	What's different about EnergyPlus Input and Output? . . . . .	25
1.1.1	EnergyPlus Input Processing . . . . .	25
1.1.2	General Input Rules . . . . .	26
1.1.3	EnergyPlus Output Processing . . . . .	27
1.2	IDD Conventions . . . . .	27
1.2.1	IDD – IP Units . . . . .	31
1.3	Input – Output Descriptions (Document) . . . . .	33
1.3.1	Input Descriptions . . . . .	33
1.3.2	Output Descriptions . . . . .	34
1.4	Using EnergyPlus as a Library . . . . .	36
1.4.1	State API . . . . .	37
1.4.2	Functional API . . . . .	38
1.4.3	Runtime API . . . . .	39
1.4.4	Data Exchange API . . . . .	40
1.4.5	Full Examples . . . . .	43
1.4.6	Building and Linking . . . . .	43
1.5	Group – Simulation Parameters . . . . .	43
1.5.1	Version . . . . .	44
1.5.2	Timestep . . . . .	44
1.5.3	ConvergenceLimits . . . . .	45
1.5.4	Building . . . . .	47
1.5.5	SurfaceConvectionAlgorithm:Inside . . . . .	54
1.5.6	SurfaceConvectionAlgorithm:Outside . . . . .	55
1.5.7	HeatBalanceAlgorithm . . . . .	56
1.5.8	HeatBalanceSettings:ConductionFiniteDifference . . . . .	57
1.5.9	ZoneAirHeatBalanceAlgorithm . . . . .	58
1.5.10	ZoneAirContaminantBalance . . . . .	59
1.5.11	ShadowCalculation . . . . .	60
1.5.12	Output:Diagnostics . . . . .	64
1.5.13	Output:DebuggingData . . . . .	65
1.5.14	Output:PreprocessorMessage . . . . .	66
1.5.15	ZoneCapacitanceMultiplier:ResearchSpecial . . . . .	66
1.5.16	SimulationControl . . . . .	67
1.5.17	PerformancePrecisionTradeoffs . . . . .	69
1.5.18	HVACSystemRootFindingAlgorithm . . . . .	77

1.5.19	Meter:Custom . . . . .	78
1.5.20	Meter:CustomDecrement . . . . .	79
1.5.21	Custom Meter Examples . . . . .	81
1.5.22	Simulation Parameter Outputs . . . . .	82
1.6	Group – Compliance Objects . . . . .	82
1.6.1	Compliance:Building . . . . .	82

# Chapter 1

## Input-Output Reference

This document is intended to be an encyclopedic reference for the EnergyPlus Input Data Dictionary (IDD), Input Data File (IDF) and potential resultant outputs (various output files).

The following descriptions are “grouped” by the elements in the IDD (ref: Getting Started Document and the IDD Conventions). In some cases, the descriptions of reporting will be done for an object (e.g., Lighting electrical consumption or thermal comfort value for a group of people) and in some cases for the entire group (e.g., ambient condition reports).

### 1.1 What’s different about EnergyPlus Input and Output?

The usual procedure for non-interactive programs is to process all the input necessary to “do the job”, perform the actions required by the input, and somewhere along the way produce reports on the actions. Usually, there will be error messages on incorrect input statements and/or incorrect conditions detected during processing. Usually, the input is echoed in its entirety so that the context of errors is shown clearly.

Results are typically output into reports as well as a compilation of various inputs reformatted into different groupings than were originally entered (defaults filled in, etc.)

EnergyPlus does all the above. However, some nuances are different from the usual actions.

#### 1.1.1 EnergyPlus Input Processing

1) EnergyPlus is compiled with a specific the data dictionary (Energy+.idd) and the input data file (in.idf) is read prior to doing anything else. Only after this is done does processing start. **HOWEVER**, the input processor only knows as much as the data dictionary has told it. It knows which fields should be alpha and which should be numeric. All of this information (including the IDD) is echoed to the audit file (audit.out) in case errors occur. Most of the errors show up (out of context) in the standard error file (eplusout.err) – there might be enough information to decipher where the error is or you may have to look at the more inclusive audit file. Invalid numeric fields are detected during this processing and default numeric fields are filled. For more information on the IDD, its structure and implications, please see the IDD Conventions discussion below.

2) The biggest difference between EnergyPlus and more traditional input processing is that EnergyPlus is modular in its actual filling in the details for the simulation. Because of the modular structure of EnergyPlus, each module is responsible for “getting” its own input. It receives this input from the input processor in the form of alpha and numeric fields. Each module typically gets

all its input the first time it is called. The implication for the user is that error messages may show up in somewhat peculiar places. A further implication is that no order is needed in the input data file! Data that is not needed by a particular simulation is not processed.

3) The data dictionary provides the capability to do “automatic” range checking on numeric fields as well as fill in numeric defaults. Both filling in defaults and “automatic” range checking are done when the data is read. Other checks may need a combination of fields and won’t be done until the data is “processed” (after the simulation starts).

4) A couple of other differences that might not be true in other programs: Blanks are significant in alpha fields **SO** DesignDay is not the same as Design Day (1 space between Design and Day) nor Design Day (2 spaces between Design and Day). Alpha objects, however, are case insensitive SO DesignDay is the same as ‘designday’ or ‘**SizingPeriod:DesignDay**’.

### 1.1.2 General Input Rules

Rules shown here are for the input data files. Rules about the Input Data Dictionary are shown in the Interface Developer’s Guide (there is much similarity and overlap) but most users can view the IDD (Input Data Dictionary) as an additional quick reference for EnergyPlus.

The input data file is the primary file that EnergyPlus uses to create the building simulation. The only additional files are referenced by certain objects (such as the **Schedule:File** object). The input is order-independent; data can appear in any order and will be retrieved and sorted as necessary by the EnergyPlus simulation modules. In addition, EnergyPlus allocates everything dynamically, so there are no limitations as to number of zones, surfaces, etc.

- The initial line of an input object MUST have a comma or semicolon.
- Fields do not extend over line boundaries. Usually, if a comma or (as appropriate) semi-colon is not the last field value on a line, one will be inserted. Of course, several fields may appear on a single line as long as they are comma separated. (And the last could be followed by a semi-colon).
- Commas delimit fields – therefore, no fields can have embedded commas. No error will occur but you won’t get what you want. You cannot surround a field with “ to accommodate commas in the fields.
- Blank lines are allowed.
- The comment character is a exclamation “!”. Anything on a line after the exclamation is ignored.
- Input records (aka input line length) can be up to 500 characters in length. If you go over that, no error will occur but you won’t get what you want.
- Each Alpha string in the input data file (aka alpha field length) can be up to 100 characters in length. Anything beyond that is truncated. This would apply to all names (such as zone name, node name, schedule name) in fields.
- Each Alpha string (including Section and Class/Object keywords) is mapped to UPPER case during processing, unless the “*retaincase*” flag marks the field in the IDD. Get routines from

the EnergyPlus code that use the Section and Object keywords automatically map to UPPER case for finding the item. The primary drawback with this is that error messages coming out of the input processor will be in UPPER case and may not appear exactly as input.

- Special characters, such as tabs, should NOT be included in the file. However, tabs can be accommodated and are turned into spaces.
- All numbers can be flexibly input and are processed into single precision variables (i.e. 1.0, 1.000, 1, .1E+1 are all processed equally).

### 1.1.3 EnergyPlus Output Processing

1. Unlike the usual formatted output text formatted reports, EnergyPlus usual output is either at the summary or at the detailed (variable) level. Summary reports exist for many inputs as well as sizing results. The more detailed variable level reporting is produced as “stream of consciousness” (as the simulation happens) and must be post-processed for more sensible viewing. Note that the terms “variable” and “output variable” (accessed by the **Output:Variable** and/or **Output:Meter** objects) are used interchangeably in this document.
2. Most EnergyPlus reporting can be readily viewed in current spreadsheet programs – or other software that can process “delimited variable” reports. In these kind of reports, each “column” is separated from the next by a “delimiter”. Typical delimiters are “comma” and “tab”. Gradually, EnergyPlus reporting is moving from all comma separated reports to allow the user to select the delimiter via “style” objects.
3. Styled reports allow for more selectable output reporting but also increase the number of output files as we have chosen to create the report names with extensions that typify the actual reporting. Depending on the reporting, these can be:
  - Tab – reports with a .tab extension have tabs as the delimiter. These report files (directly from EnergyPlus) will be named something like “eplus<xxx>.tab” where the <xxx> is a short name of the kind of report (e.g. Zsz for Zone Sizing, Map for Daylighting Map)
  - Csv – reports with a .csv extension have commas as the delimiter. These are also specially formatted for use in spreadsheets (such as the compilation of results from the eplusout.eso file into the eplusout.csv file using the default post-processor program).
  - Txt – reports with a .txt extension have spaces as the “delimiter” but only certain of these are really formatted the way you might expect: where multiple spaces make printing with a non-proportional font would produce readable output.
  - Html – reports with a .html extension are “web-browser” ready.

## 1.2 IDD Conventions

The following is a basic description of the structure of the IDD (it's actually taken directly from the IDD file). As noted within, ! signifies a comment character as does the \. \ has also been adopted as a convention for including more specific comments about each field in an object. These have been used with success in the IDFEeditor and it is hoped the flexibility will provide other interface developers with useful information.

```

! IDD_Version ${CMAKE_VERSION_MAJOR}.${CMAKE_VERSION_MINOR}.${CMAKE_VERSION_PATCH}
! IDD_BUILD ${CMAKE_VERSION_BUILD}
! ****
! This file is the Input Data Dictionary (IDD) for EnergyPlus.
! The IDD defines the syntax and data model for each type of input "Object."
! Lines in EnergyPlus input files (and IDD) are limited to 500 characters.

! Object Description
-----
! To define an object (a record with data), develop a key word that is unique
! Each data item to the object can be A (Alphanumeric string) or N (numeric)
! Number each A and N. This will show how the data items will be put into the
! arrays that are passed to the Input Processor "Get" (GetObjectItem) routines.
! All alpha fields are limited to 100 characters. Numeric fields should be
! valid numerics (can include such as 1.0E+05) and are placed into double
! precision variables.

! NOTE: Even though a field may be optional, a comma representing that field
! must be included (unless it is the last field in the object). Since the
! entire input is "field-oriented" and not "keyword-oriented", the EnergyPlus
! Input Processor must have some representation (even if blank) for each
! field.

! Object Documentation
-----
! In addition, the following special comments appear one per line and
! most are followed by a value. Comments may apply to a field or the object
! or a group of objects.

! Field-level comments:

! \field      Name of field
!             (should be succinct and readable, blanks are encouraged)

! \note       Note describing the field and its valid values. If multiple lines,
!             start each line with \note. Limit line length to 100 characters.

! \required-field To flag fields which must have a value. If the idf input is blank and
!                 there is a \default, then the default will be used. However, as of v8.6.0
!                 the use of \required-field and \default on the same field is discouraged
!                 and instances with both have been changed.
!                 (this comment has no "value")

! \begin-extensible Marks the first field at which the object accepts an extensible
!                   field set. A fixed number of fields from this marker define the
!                   extensible field set, see the object code \extensible for
!                   more information.

! \units       Units (must be from EnergyPlus standard units list)
!             EnergyPlus units are standard SI units

! \ip-units    IP-Units (for use by input processors with IP units)
!             This is only used if the default conversion is not
!             appropriate.

! \unitsBasedOnField For fields that may have multiple possible units, indicates
!                     the field in the object that can be used to determine
!                     the units. The field reference is in the A2 form.

! \minimum     Minimum that includes the following value

! \minimum>   Minimum that must be > than the following value

! \maximum     Maximum that includes the following value

! \maximum<   Maximum that must be < than the following value

! \default     Default for the field (if N/A then omit entire line). If a default is
!             added to an existing field, then \required-field should be removed if present.
!             Defaults are filled in only if the field is within \min-fields, or the actual

```

```

object is longer than this field.

\deprecated This field is not really used and will be deleted from the object.
The required information is gotten internally or
not needed by the program.

\autosizable Flag to indicate that this field can be used with the Auto
Sizing routines to produce calculated results for the
field. If a value follows this, then that will be used
when the "Autosize" feature is flagged. To trigger
autosizing for a field, enter Autosize as the field's
value. Only applicable to numeric fields.

\autocalculatable Flag to indicate that this field can be automatically
calculated. To trigger auto calculation for a field, enter
Autocalculate as the field's value. Only applicable to
numeric fields.

\type Type of data for the field -
    integer
    real
    alpha      (arbitrary string),
    choice     (alpha with specific list of choices, see
                \key)
    object-list (link to a list of objects defined elsewhere,
                 see \object-list and \reference)
    external-list (uses a special list from an external source,
                  see \external-list)
    node       (name used in connecting HVAC components)

\retaincase Retains the alphabetic case for alpha type fields

\key Possible value for "\type choice" (blanks are significant)
      use multiple \key lines to indicate all valid choices

\object-list Name of a list of user-provided object names that are valid
            entries for this field (used with "\reference")
            see Zone and BuildingSurface:Detailed objects below for
            examples.
** Note that a field may have multiple \object-list commands.

\external-list The values for this field should be selected from a special
            list generated outside of the IDD file. The choices for the
            special lists are:
                autoRDDvariable
                autoRDDmeter
                autoRDDvariableMeter
When one of these are selected the options for the field
are taken from the RDD or MDD file or both.

\reference Name of a list of names to which this object belongs
           used with "\type object-list" and with "\object-list"
           see Zone and BuildingSurface:Detailed objects below for
           examples:

           Zone,
           A1 , \field Name
           \type alpha
           \reference ZoneNames

           BuildingSurface:Detailed,
           A4 , \field Zone Name
           \note Zone the surface is a part of
           \type object-list
           \object-list ZoneNames

For each zone, the field "Name" may be referenced
by other objects, such as BuildingSurface:Detailed, so it is
commented with "\reference ZoneNames"
Fields that reference a zone name, such as BuildingSurface:Detailed's

```

```

!           "Zone Name", are commented as
!           "\type object-list" and "\object-list ZoneNames"
!           ** Note that a field may have multiple \reference commands.
!           ** This is useful if the object belongs to a small specific
!           object-list as well as a larger more general object-list.

! Object-level comments:

! \memo      Memo describing the object. If multiple lines, start each line
!             with \memo.
!             Limit line length to 100 characters.

! \unique-object To flag objects which should appear only once in an idf
!                 (this comment has no "value")

! \required-object To flag objects which are required in every idf
!                   (this comment has no "value")

! \min-fields Minimum number of fields that should be included in the
!               object. If appropriate, the Input Processor will fill
!               any missing fields with defaults (for numeric fields).
!               It will also supply that number of fields to the "get"
!               routines using blanks for alpha fields (note -- blanks
!               may not be allowable for some alpha fields).

! \obsolete   This object has been replaced though is kept (and is read)
!             in the current version. Please refer to documentation as
!             to the dispersal of the object. If this object is
!             encountered in an IDF, the InputProcessor will post an
!             appropriate message to the error file.
!             usage: \obsolete New=>[New object name]

! \extensible:<#> This object is dynamically extensible -- meaning, if you
!                  change the IDD appropriately (if the object has a simple list
!                  structure -- just add items to the list arguments (i.e. BRANCH
!                  LIST). These will be automatically redimensioned and used during
!                  the simulation. <#> should be entered by the developer to signify
!                  how many of the last fields are needed to be extended (and EnergyPlus
!                  will attempt to auto-extend the object). The first field of the first
!                  instance of the extensible field set is marked with \begin-extensible.

! \begin-extensible See previous item, marks beginning of extensible fields in
!                   an object.

! \format     The object should have a special format when saved in
!                 the IDF Editor with the special format option enabled.
!                 The options include SingleLine, Vertices, CompactSchedule,
!                 FluidProperties, ViewFactors, and Spectral.
!                 The SingleLine option puts all the fields for the object
!                 on a single line. The Vertices option is used in objects
!                 that use X, Y and Z fields to format those three fields
!                 on a single line.
!                 The CompactSchedule formats that specific object.
!                 The FluidProperty option formats long lists of fluid
!                 properties to ten values per line.
!                 The ViewFactor option formats three fields related to
!                 view factors per line.
!                 The Spectral option formats the four fields related to
!                 window glass spectral data per line.

! \reference-class-name Adds the name of the class to the reference list
!                      similar to \reference.

! Group-level comments:

! \group      Name for a group of related objects

! Notes on comments
! -----

```

```
!
! 1. If a particular comment is not applicable (such as units, or default)
! then simply omit the comment rather than indicating N/A.
!
! 2. Memos and notes should be brief (recommend 5 lines or less per block).
! More extensive explanations are expected to be in the user documentation
```

### 1.2.1 IDD – IP Units

In addition, the IDD contains indications of IP (inch-pound) units for the EnergyPlus standard SI (Systems International) units. These may be used by input and output interfaces to display values in the IP system. As noted, if the IP units are “standard” (first block below), then no \ip-units is expected in the field. Note that for some fields – due to their multiple use (for example, schedule values) – there cannot be a ip-unit designation.

```
! Default IP conversions (no \ip-units necessary)
! $/(m3/s)          = >  $(/ft3/min)      0.000472000059660808
! $(/W/K)           = >  $(/Btu/h-F)     0.52667614683731
! $/kW              = >  $(/kBtu/h)      0.293083235638921
! $/m2              = >  $/ft2            0.0928939733269818
! $/m3              = >  $/ft3            0.0283127014102352
! (kg/s)/W          = >  (lbm/sec)/(Btu/hr) 0.646078115385742
! 1/K               = >  1/F              0.5555555555555556
! 1/m               = >  1/ft             0.3048
! A/K               = >  A/F              0.5555555555555556
! C                 = >  F                1.8 (plus 32)
! cm                = >  in               0.3937
! cm2              = >  inch2            0.15500031000062
! deltaC            = >  deltaF            1.8
! deltaJ/kg         = >  deltaBtu/lb    0.0004299

## 1.3 Input – Output Descriptions (Document)

### 1.3.1 Input Descriptions

In the descriptions below, the fields for each input object will be described but the Energy+.idd descriptions will not be shown. Refer to the actual Energy+.idd file for complete specifications. Energy+.idd is a text file that can be viewed with many text editors or word processors. The **Site:Location** object will serve as an example.

```

Site:Location,
  \unique-object
  \min-fields 5
A1 , \field Name
  \required-field
  \type alpha
N1 , \field Latitude
  \units deg
  \minimum -90.0
  \maximum +90.0
  \default 0.0
  \note + is North, - is South, degree minutes represented in decimal (i.e. 30 minutes is .5)
  \type real
N2 , \field Longitude
  \units deg
  \minimum -180.0
  \maximum +180.0
  \default 0.0
  \note - is West, + is East, degree minutes represented in decimal (i.e. 30 minutes is .5)
  \type real
N3 , \field Time Zone
  \note basic these limits on the WorldTimeZone Map (2003)
  \units hr
  \minimum -12.0
  \maximum +14.0
  \default 0.0

```

```
\note Time relative to GMT. Decimal hours.
\type real
N4 ; \field Elevation
\units m
\minimum -300.0
\maximum 8900.0
\default 0.0
\type real
```

The IDD excerpt above is the complete definition as seen in the IDD file.

First, the object name is given. ([Site:Location](#)) This is followed by a comma in both the definition (IDD) and in an input file (IDF). In fact, all fields except the terminating field of an IDD class object and IDF object are followed by commas. The final field in an IDD class object or in an IDF object is terminated by a semi-colon.

Next is an alpha field, the location name. As noted above, for input, spaces are significant in this field. The main inputs for [Site:Location](#) are numeric fields. These are numbered (as is the alpha field) for convenience. The \ designations will show various information about the objects as described above in the IDD conventions discussion. Of importance for reading this document are the units and possible minimum and maximum values for a field.

There is automatic processing of the \minimum, \maximum and \default data for numeric fields. Any infractions of the \minimum, \maximum fields are automatically detected and messages will appear in the standard error file. After all the input is checked, infractions will cause program termination (before the bulk of the simulation is completed). Defaults are also enforced if you leave the numeric field blank.

Some objects need all the parameters listed by the definition; some do not. In the descriptions that follow, we will try to indicate which parts are optional. Usually, these will be the last fields in the object input or definition. Even if items are not used for a particular object (e.g. Multiplier in the [FenestrationSurface:Detailed](#) and type = Door), the field must be included unless it is the *last field in the object*. So, for this instance, one must include a multiplier field (must be numeric and would need to obey any \minimum, \maximum rules) for doors.

Two spreadsheet files are included with the installation:

- ExampleFiles.xls – shows many details about the included example files including highlights of features.
- ExampleFiles-ObjectsLink.xls – shows, for each object, the first three occurrences of that object in an example file.

### 1.3.2 Output Descriptions

In the descriptions below, we will endeavor to have each object's output displayed as well as each of the outputs described. The output variables for a run are selected by choosing the [Output:VariableDictionary](#) object. This object displays the available output variables for a run on the **eplusout.rdd** (regular variables) and **eplusout.mdd** (meter variables) files. Two significant styles are available for these displays and the descriptions below may have one for some objects and another for other objects. The variables are the same but will look a bit different. For clarity, the two displays are shown below:

Note that the IDF-Editor can interpret both sets of files and assist you in getting output variables into your input files. But you will have to successfully run your input file first.

The Simple (or regular) display looks like the following figure and is interpreted:

**Zone/HVAC** – when the output is produced at the “Zone” timestep (ref: number of timesteps in each hour) or at the “HVAC” aka System timestep (which can vary for each hour).

**Average/Sum** – whether this is a averaged value over the reporting period (such as a temperature or rate) or whether this is a summed value over the reporting period. Reporting periods are specified in the **Output:Variable** or **Output:Meter** objects.

<**Variable Name**> – The variable name one uses for reporting is displayed (e.g., Site Outdoor Drybulb Temperature) along with the units (e.g., [C]).

Example from the **eplusout.rdd** file:

- Zone,Average,Site Outdoor Air Drybulb Temperature [C]
- Zone,Average,Site Outdoor Air Dewpoint Temperature [C]
- Zone,Average,Site Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Site Outdoor Air Humidity Ratio [kgWater/kgAir]
- Zone,Average,Site Outdoor Air Relative Humidity [%]
- Zone,Average,Site Outdoor Air Barometric Pressure [Pa]
- Zone,Average,Wind Speed [m/s]
- Zone,Average,Site Wind Direction [deg]
- Zone,Average,Site Sky Temperature [C]
- HVAC,Sum,Zone Air System Sensible Heating Energy [J]
- HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
- HVAC,Average,Zone Air System Sensible Heating Rate [W]
- HVAC,Average,Zone Air System Sensible Cooling Rate [W]
- HVAC,Average,Zone Air Temperature [C]
- HVAC,Average,Zone Thermostat Air Temperature [C]

Note that the **eplusout.mdd** file is similar, but meters are only available at the Zone timestep.

- Zone,Meter,Electricity:Facility [J]
- Zone,Meter,ExteriorLights:Electricity [J]
- Zone,Meter,Grounds Lights:ExteriorLights:Electricity [J]
- Zone,Meter,EnergyTransfer:Facility [J]
- Zone,Meter,EnergyTransfer:Building [J]
- Zone,Meter,EnergyTransfer:Zone:R13WALL WALLS [J]

The IDF display has all the same information in an IDF-ready form (i.e., you could copy and paste it into your input file using a text editor).

Example from the **eplusout.rdd** file:

- **Output:Variable,\***,Site Outdoor Air Drybulb Temperature,hourly; !- Zone Average [C]
- **Output:Variable,\***,Site Outdoor Air Dewpoint Temperature,hourly; !- Zone Average [C]
- **Output:Variable,\***,Site Outdoor Air Wetbulb Temperature,hourly; !- Zone Average [C]
- **Output:Variable,\***,Site Outdoor Air Humidity Ratio,hourly; !- Zone Average [kgWater/kgAir]
- **Output:Variable,\***,Site Outdoor Air Relative Humidity,hourly; !- Zone Average [%]
- **Output:Variable,\***,Site Outdoor Air Barometric Pressure,hourly; !- Zone Average [Pa]
- **Output:Variable,\***,Zone Air System Sensible Heating Energy,hourly; !- HVAC Sum [J]
- **Output:Variable,\***,Zone Air System Sensible Cooling Energy,hourly; !- HVAC Sum [J]
- **Output:Variable,\***,Zone Air System Sensible Heating Rate,hourly; !- HVAC Average [W]
- **Output:Variable,\***,Zone Air System Sensible Cooling Rate,hourly; !- HVAC Average [W]
- **Output:Variable,\***,Zone Air Temperature,hourly; !- HVAC Average [C]
- **Output:Variable,\***,Zone Thermostat Air Temperature,hourly; !- HVAC Average [C]

All of the same information appears in a slightly different form and defaults to “hourly” reporting frequency (which, of course, can be changed when you put it into your input file). The “\*” is preselected so that you would be reporting for all those items.

## 1.4 Using EnergyPlus as a Library

This section is specifically related to calling EnergyPlus as a function from other clients, including C programs and Python scripts. For information on using Python Plugins (Python EMS), see section [1.45](#).

Since its birth, interacting with EnergyPlus has been essentially limited to creating an input file and calling on the EnergyPlus binary to run and produce results. For a long time, there has been a very small API made available to allow limited access to running a simulation from a client by calling a function, however, it was never widely publicized, and had significant issues. As of version 9.3, a proper API has been developed, which builds on a number of important developments, including:

- The Energy Management System, which was the first method to allow reading and writing simulation data while a simulation was running, and allowing user-defined scripts to be executed to alter simulation data.
- The EnergyPlus unit test structure, which has, as a side-effect, enabled the ability to “reset” the state of a simulation, and re-run another, in the same memory space.

Release history notes:

- Version 9.3 included the first version of the modern API in EnergyPlus.
- As of version 9.4, the API was improved with the ability to more reliably “reset” the simulation state. This caused some breaking changes in the API, which are expected to be very rare moving forward.
- Then as of version 9.5, EnergyPlus became thread-safe. By refactoring 17,000 global and static variables in the program, the state object now holds the entire state of the program, and threads will not cross-talk.
- With the release of EnergyPlus 9.6, another major enhancement was made that allowed API clients to execute input files that included Python Plugins. The original implementation had a limitation that kept the two from working together, but this was remedied so that interfaces that call the API can simultaneously execute files with Python Plugins.

Interface developers that have been building on top of EnergyPlus have primarily interacted with the simulation in the traditional manner. The interface would create an input file in a directory, copy in weather data and any other supporting data, and then kick off a simulation in that directory. The interface could grab output messages from the simulation, but that was essentially it. The interface just had to wait until EnergyPlus completed, check data in the output files, and decide what to do next. Grabbing any sort of data from the simulation during a run, even just progress, was highly difficult.

The EnergyPlus API has been created to change that situation and open new doors into the simulation program and the opportunity to embed EnergyPlus into vastly more workflows and applications. A new formal EnergyPlus API is implemented that allows interacting with different “categories” of the simulation. Technically speaking, the categories are not different, as they operate using the same API mechanics. The categorization is purely organizational. In the following subsections, the API is laid out with examples in both C and Python. Full API documentation will be provided separate from this document. Check the release notes for your specific release for more information.

### 1.4.1 State API

The state of an EnergyPlus represents the entire contents of a running simulation. Everything from the current time step to the water side economizer operating part load ratio is tracked in the state of a running simulation. Since the birth of EnergyPlus, the state of the simulation was hung on the global program state, with no explicit object owning and managing the data. This was perfectly acceptable because the only real use of EnergyPlus was to execute the binary (energyplus.exe) and wait for it to finish and inspect the outputs. However, this has proved to be a burden when trying to push EnergyPlus into new applications, and as such, the team has worked to move much of the global state into a state class which can then manage the data on itself. From an internal-to-EnergyPlus perspective, this means that functions will access variables on a class that is passed around throughout the program. From an API-client perspective, this means that the client will need to create a state instance and pass it into the simulation when asking the simulation to do most operations.

Prior to calling into most of the API functions, the API client must create a new state instance. This state instance is not to be directly accessed by the client, but instead the client must simply be a courier of this state instance and pass it in and out of the API calls. Whenever the client is done with that instance, the instance can be reset to be prepped for another run of EnergyPlus, or destroyed if the client is done with it.

An example of this in C is listed here:

```
#include <EnergyPlus/api/state.h>

int main(int argc, const char * argv[]) {
    EnergyPlusState state = stateNew();
    stateReset(state);
    stateDelete(state);
    printf("Wow this was a boring use case\n");
}
```

---

That does not do much. But moving through the rest of the API functions, it will become clear that this is at the core of an EnergyPlus API workflow.

In Python, that same example is similar:

```
from pyenergyplus.api import EnergyPlusAPI

api = EnergyPlusAPI()
state = api.state_manager.new_state()
api.state_manager.reset_state(state)
api.state_manager.delete_state(state)
print("Wow even boring in Python!?)")
```

---

## 1.4.2 Functional API

The “Functional” API allows for users to call into the EnergyPlus binary and request static information. Examples of this information include fluid property data (currently only pure water, but glycol mixtures will be added), refrigerant property data (currently only steam), and psychrometric properties.

To interact with the fluid property data, the user will create a fluid property class instance. Once an instance is available, the user will call methods on that instance. To interact with the refrigerant property data, the user will also create a refrigerant class and access data through methods. For psychometrics, in C the function calls do not need to create an instance, however, in Python, a small class captures the psychometric functions for organization.

While some functionality in these property routines are stateless from the perspective of the EnergyPlus simulation engine, an instance of the EnergyPlus “state” class is required to be passed in.

An example of exercising the functional API in C is listed here:

```
#include <EnergyPlus/api/func.h>
#include <EnergyPlus/api/state.h>

int main(int argc, const char * argv[]) {
    EnergyPlusState state = stateNew();
    initializeFunctionalAPI(state);

    Glycol glycol = NULL;
    glycol = glycolNew(state, "WatEr");
    Real64 specificHeat = glycolSpecificHeat(state, glycol, 35.0);
    glycolDelete(state, glycol);

    Refrigerant refrig = NULL;
    refrig = refrigerantNew(state, "SteaM");
```

```

Real64 satPress = refrigerantSaturationPressure(state, refrig, 100.0);
refrigerantDelete(state, refrig);

Real64 rh = psyRhFnTdbWPb(state, 24, 0.009, 101325); // psychrometrics are evaluated directly
}

```

It is quite minimal, objects are constructed, methods are called, and objects are destructed. Note that the `initializeFunctionalAPI` function must be called once to setup the program. Note that the constructor function arguments are case-insensitive. Also note that no simulation has been executed here, this is purely calling into the library to evaluate functions.

The same operations, but in Python are listed here:

```

from pyenergyplus.api import EnergyPlusAPI

api = EnergyPlusAPI()
state = api.state_manager.new_state()

glycol = api.functional.glycol(state, u"water")
cp = glycol.specific_heat(state, 35.0)

refrigerant = api.functional.refrigerant(state, "steam")
satPress = refrigerant.saturation_pressure(state, 100.0)

psychrometrics = api.functional.psychrometrics(state, )
rh = psychrometrics.relative_humidity_b(state, 24, 0.009, 101325)

```

Some subtle differences are present. In Python, the client creates an instance of an `EnergyPlusAPI` class to access all methods. Functional category API methods are accessed via the `EnergyPlusAPI.functional` variable. Note that in Python, in contrast to C, the psychrometric functions also live on a class that must be constructed.

### 1.4.3 Runtime API

The “Runtime” API allows for users to hook into a running simulation. The client creates functions, and using this runtime API, they can register these functions to be called back at specific points in a simulation. Once registered, this API includes a function to start the simulation. There are a number of calling points available to hook in a callback function. For information on the different available calling points, see the EMSApplicationGuide documentation packaged with EnergyPlus. For exact naming conventions on the C and Python registration functions, see either the C header or Python API file, or the API documentation that will be made available separate from the installer. See the release notes for information on subsequent documentation.

A minimal approach demonstrating the runtime API in C would be the following:

Note that as of EnergyPlus 9.4, due to the change in handling simulation state, the form of the callback function has changed. While a simulation is running, there is a matched state object that must be passed in and out of the program to perform operations. This has already been demonstrated in the above functional API example, but in this case, the state change is more pronounced because the callback function must accept a state argument. The reason the callback must accept the state argument is because while inside a callback, it is expected that the client code will then call into EnergyPlus to read/write data, and the state must be passed back in. Basically, the client must be a reliable courier of the state object.

```

#include <EnergyPlus/api/runtime.h>
#include <EnergyPlus/api/state.h>

void dummyCallbackFunction(EnergyPlusState state) {
    printf("Hmm I could use my state argument to call back into EnergyPlus to do stuff, great!\n");
}

```

```

}

int main(int argc, const char * argv[]) {
    callbackAfterNewEnvironmentWarmupComplete(state, dummyCallbackFunction);
    energyplus(state, argc, argv);
    stateReset(state); // note previously registered callbacks are cleared here
    callbackAfterNewEnvironmentWarmupComplete(state, dummyCallbackFunction);
    energyplus(state, argc, argv);
}

```

The code is straightforward, though excessively minimal. A minimal function is created, which accepts one argument - a state object, and does nothing. This function is then passed to a callback registration function via the runtime API. EnergyPlus is executed, passing along any command line arguments that are received by the test program. This is a convenience because the energyplus function expects arguments just like the EnergyPlus(.exe) program, so the test script would have the same command line capabilities as EnergyPlus itself. For this code, it could be executed with something like: `program.exe -D /path/to/input.idf`. Once EnergyPlus is complete, the state object is reset, the callback is re-registered, and EnergyPlus is run again. Since the test script is complete at this point, there is no need to reset the state again.

The code is strikingly similar in Python:

```

import sys
from pyenergyplus.api import EnergyPlusAPI

def dummy_callback_function(state_argument):
    print("My argument is called state_argument to avoid duplicating the outer variable below called state")
    """

api = EnergyPlusAPI()
state = api.state_manager.new_state()
api.runtime.callback_begin_new_environment(state, dummy_callback_function)
api.runtime.run_energyplus(state, sys.argv[1:])
api.state_manager.reset_state(state)
api.runtime.callback_begin_new_environment(state, dummy_callback_function)
api.runtime.run_energyplus(state, sys.argv[1:])

```

Once again, a dummy function is created, then registered, followed by a call to run EnergyPlus (passing along the relevant command line arguments), the state is cleared, then the function is registered again and EnergyPlus is run a second time. Note that when calling EnergyPlus as a library, you should just pass the arguments, not the filename itself. In Python, the argv variable will have the filename as the first item in the list, so this example trims that off.

#### 1.4.4 Data Exchange API

The “Data Exchange” API allows for users to interact with simulation data. There are some functions in this API that are suitable only for Python Plugin workflows, and they will not be discussed here. For more information on using that workflow, see section [1.45](#). For this API, five areas are available: variables, meters, “internal” variables, simulation parameters, and actuators. They are described in a language-agnostic sense first, then actual examples are provided in C and Python below.

**Variables** Variables represent time series output variables in the simulation. There are thousands of variables made available based on the specific configuration. A user typically requests variables to be in their output files by adding `Output:Variable` objects to the input file. It is important to note that if the user does not request these variables, they are not tracked, and thus not available on the API.

In an API workflow, the client would interact with variables in three steps. First the user will either specify the output as requested in the input file provided, or call a variable request function to mark the variable as requested. Second the user will call to lookup a variable ID/handle, passing in the variable type name and key. Third the variable value can be looked up while a simulation is running by calling a get-value function on the API.

**Meters** Meters represent groups of variables which are collected together, much like a meter on a building which represents multiple energy sources. Meters are handled the same way as variables, except that meters do not need to be requested prior running a simulation. From an API standpoint, a client must simply get a handle to a meter by name, and then access the meter value by using a get-value function on the API.

**Internal Variables** The name “internal variable” is used here as it is what these variables were called in the original EMS implementation. Another name for these variables could be “static” variables. Basically, these variables represent data that does not change throughout a simulation period. Examples include calculated zone volume or autosized equipment values. These values are treated just like meters, you use one function to access a handle ID, and then use this handle to lookup the value.

**Simulation Parameters** A number of parameters are made available as they vary through the simulation, including the current simulation day of week, day of year, hour, and many other things. These do not require a handle, but are available through direct function calls.

With these read-only data exchange items available, there are already a number of new possibilities. As an example, an EnergyPlus interface developer could very easily change from just executing the EnergyPlus program, to calling EnergyPlus as a library function. This would unlock the potential to not only get better progress status updates, but the interface could also request and lookup values of some energy meters or other output variables, and present this to the user graphically while the simulation is running. However, much more power comes with the addition of actuators, described next.

**Actuators** Actuators are the way that users modify the program at runtime using custom logic and calculations. Not every variable inside EnergyPlus can be actuated. This is intentional, because opening that door could allow the program to run at unrealistic conditions, with flow imbalances or energy imbalances, and many other possible problems. Instead, a specific set of items are available to actuate, primarily control functions, flow requests, and environmental boundary conditions. These actuators, when used in conjunction with the runtime API and data exchange variables, allow a user to read data, make decisions and perform calculations, then actuate control strategies for subsequent time steps.

Actuator functions are similar, but not exactly the same, as for variables. An actuator handle/ID is still looked up, but it takes the actuator type, component name, and control type, since components may have more than one control type available for actuation. The actuator can then be “actuated” by calling a set-value function, which overrides an internal value, and informs EnergyPlus that this value is currently being externally controlled. To allow EnergyPlus to resume controlling that value, there is an actuator reset function as well.

A special note about data exchange. Variables, meters, and actuators are not immediately available as soon as the program starts. The memory associated with these along with the

bookkeeping, must be set up during program initialization. There is a risk that the variables requested are not set up by the first API callback point. This is intentional because some API callbacks may want to be called this early. To avoid problems, a function is available on this API that will allow a client to check if the API data is “fully ready”. For almost all applications, if this is not ready, the client should just return from the callback and let EnergyPlus continue, and wait until it is ready before doing any manipulation.

It is difficult (impossible?) to exercise the data exchange API without at least also demonstrating the runtime API. In order to exchange data with the simulation, you must first create a runtime callback function and register that, then execute EnergyPlus, and finally wait until EnergyPlus calls your callback function. At this point, you can then perform data exchange. Minimal examples that tie the runtime and data exchange APIs together are shown here, first in C:

```
#include <EnergyPlus/api/datatransfer.h>
#include <EnergyPlus/api/runtime.h>
#include <EnergyPlus/api/state.h>

int outdoorDewPointActuator = -1;
int outdoorTempSensor = -1;
int handlesRetrieved = 0;

void afterZoneTimeStepHandler(EnergyPlusState state)
{
    if (handlesRetrieved == 0) {
        if (!apiDataFullyReady(state)) return;
        outdoorDewPointActuator = getActuatorHandle(state, "Weather Data", "Outdoor Dew Point", "Environment");
        outdoorTempSensor = getVariableHandle(state, "SITE OUTDOOR AIR DRYBULB TEMPERATURE", "ENVIRONMENT");
        handlesRetrieved = 1;
    }
    Real64 oa_temp = getVariableValue(state, outdoorTempSensor);
    setActuatorValue(state, outdoorDewPointActuator, oa_temp - 4);
}

int main(int argc, const char * argv[]) {
    callbackEndOfZoneTimeStepAfterZoneReporting(state, afterZoneTimeStepHandler);
    requestVariable(state, "SITE OUTDOOR AIR DRYBULB TEMPERATURE", "ENVIRONMENT");
    energyplus(state, argc, argv);
}
```

---

The actual operations happening in this example are completely fictional, but nevertheless demonstrate a possible minimal case. Note that the variable to be used is requested, and if the api data is not fully ready in the callback, it simply returns and waits.

And now in Python:

```
from pyenergyplus.api import EnergyPlusAPI

one_time = True
outdoor_temp_sensor = 0
outdoor_dew_point_actuator = 0

def time_step_handler(state):
    global one_time, outdoor_temp_sensor, outdoor_dew_point_sensor, outdoor_dew_point_actuator
    if one_time:
        if not api.exchange.api_data_fully_ready(state):
            return
        outdoor_temp_sensor = api.exchange.get_variable_handle(
            state, u"SITE OUTDOOR AIR DRYBULB TEMPERATURE", u"ENVIRONMENT"
        )
        outdoor_dew_point_actuator = api.exchange.get_actuator_handle(
            state, "Weather Data", "Outdoor Dew Point", "Environment"
        )
        one_time = False
    oa_temp = api.exchange.get_variable_value(state, outdoor_temp_sensor)
```

```

api.exchange.set_actuator_value(state, outdoor_dew_point_actuator, oa_temp-4)

api = EnergyPlusAPI()
state = api.state_manager.new_state()
api.runtime.callback_end_zone_timestep_after_zone_reporting(state, time_step_handler)
api.exchange.request_variable(state, "SITE OUTDOOR AIR DRYBULB TEMPERATURE", "ENVIRONMENT")
api.runtime.run_energyplus(state, sys.argv[1:])

```

Note that when strings are passed through the Python API, they are both case-insensitive, and type-insensitive. By type-insensitive, this means they can be either Python strings, or Python bytes objects. In this example, both are used, as well as mixed-casing, to demonstrate the flexibility.

### 1.4.5 Full Examples

Demonstrations of these APIs are available on the EnergyPlus repository in both Python and C form. For the latest development version, they are at [this page](#).

### 1.4.6 Building and Linking

Once you have your C or Python code scripted up, you need to actually link that code to the EnergyPlus library. The EnergyPlus install includes several relevant pieces:

```

EnergyPlusInstallRoot
- include
  - EnergyPlus
    - api
      - datatransfer.h
      - EnergyPlusAPI.h
      - func.h
      - runtime.h
      - state.h
- libenergyplusapi.so
- pyenergyplus
- api.py

```

When building C applications, the build should include the EnergyPlusInstallRoot path in your include path, so that when the client has an `#include<EnergyPlus/api/func.h>`, it will be able to find it relative to the EnergyPlus install root path. Once the code is compiled, it should be linked to the EnergyPlus shared library, which also lives in the root of the EnergyPlus install. The actual command will be different based on your system and compiler, but using gcc on Linux, for example, the command passed to the linker would be `-l/path/to/libenergyplusapi.so`.

When building Python applications, the EnergyPlusInstallRoot should be added to the search path prior to trying to import anything else. This can be accomplished through the use of environment variables, but it is also easy to do at the beginning of scripts, for example:

```

import sys
sys.path.insert(0, '/path/to/EnergyPlusInstallRoot')
from pyenergyplus import api

```

## 1.5 Group – Simulation Parameters

This group of objects influences the simulation in various ways.

## 1.5.1 Version

### 1.5.1.1 Inputs

#### 1.5.1.1.1 Field: Version Identifier

The Version object allows you to enter the proper version that your IDF was created for. This is checked against the current version of EnergyPlus and a Severe error issued (non-terminating) if it does not match the current version string. Note that versions are often significant and there is no guarantee that the older file will run in the newer versions of the program. See IDF Version Updater (Auxiliary Programs Document) for methods of changing the older files to newer versions.

## 1.5.2 Timestep

### 1.5.2.1 Inputs

#### 1.5.2.1.1 Field: Number of Timesteps per Hour

The Timestep object specifies the “basic” timestep for the simulation. The value entered here is usually known as the Zone Timestep. This is used in the Zone Heat Balance Model calculation as the driving timestep for heat transfer and load calculations. The value entered here is the number of timesteps to use within an hour. Longer length timesteps have lower values for Number of Timesteps per Hour. For example a value of 6 entered here directs the program to use a zone timestep of 10 minutes and a value of 60 means a 1 minute timestep. The user’s choice for Number of Timesteps per Hour must be evenly divisible into 60; the allowable choices are 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, and 60.

The choice made for this field has important implications for modeling accuracy and the overall time it takes to run a simulation. Here are some considerations when choosing a value:

- The solution technique used in EnergyPlus has been designed to be stable with zone timesteps of up to sixty minutes (Number Timesteps in Hour = 1). However, 60 minutes is considered a “long” timestep and it should only be used in rare occasions where there is no HVAC system, accuracy is not a concern, and short run times are critical. Such long timesteps are not recommended to use because simulation results are more accurate for shorter timesteps, of say 10 minutes or less (Number of Timesteps per Hour of 6 or more). Shorter zone timesteps improve the numerical solution of the Zone Heat Balance Model because they improve how models for surface temperature and zone air temperature are coupled together. Longer timesteps introduce more lag and lead to more a dampened dynamic response.
- Simulation run time increases with shorter timesteps or larger values for Number of Timesteps per Hour. The effect varies with the nature of the model. The user can test out different values on their particular model to understand the implications for his or her particular case. Sometimes large models with multizone HVAC and Plant systems execute nearly as fast with 15 minute timesteps as with 60 minute timesteps because fewer iterations are required in the system modeling since the prior timestep’s results are close to the final outcome of next timestep.
- The weather data files usually have 60-minute (or hourly) data. However, it does not follow that this should be used as the basis for choosing the zone timestep because:

- EnergyPlus carefully interpolates the weather data between data points for use at shorter timesteps. This is discussed in a later section: Weather Data Hourly Interpolation
- Many aspects of a model have time scales that differ from the that of the weather data. A goal of the modeling is to predict how the building will respond to the weather. However, the building’s response is not *governed* by the time scale that the weather data are available at, but rather the time scales of the dynamic performance of the thermal envelope as well as things like schedules for internal gains, thermostats, and equipment availability.
- If the model will include calculating the cost of electricity, then the user should be aware that many electric utility tariffs base charges on demand windows of a specified length of time. If the choice of Number of Timesteps per Hour is not consistent with the demand window, then unexpected results may be obtained. For reasonable prediction of the maximum rates for electricity use for in calculating demand charges, the length of the zone timestep needs to be consistent with the tariff’s demand window. The following table lists what values are consistent with various demand windows.

Demand Window	Applicable Number of Timesteps per Hour
QuarterHour	4, 12, 20, or 60
HalfHour	2, 4, 6, 10, 12, 20, 30, or 60
FullHour, Day, Week	Any

There is also second type of timestep inside EnergyPlus that is known as the System Timestep. This is a variable-length timestep that governs the driving timestep for HVAC and Plant system modeling. The user cannot directly control the system timestep (except by use of the **ConvergenceLimits** object). When the HVAC portion of the simulation begins its solution for the current zone timestep, it uses the zone timestep as its maximum length but then can reduce the timestep, as necessary, to improve the solution. The technical details of the approach are explained in the Engineering Documentation under “Integrated Solution Manager”.

Users can see the system timestep used if they select the “detailed” frequency option on an HVAC output variable (e.g. Zone Air Temperature). To contrast, the “Zone” variables will only be reported on the zone timestep (e.g. Zone Mean Air Temperature).

And, the IDF example:

```
Timestep, 6; !- Suggested default for most system simulations
```

Suggested defaults are 4 for non-HVAC simulations, 6 for simulations with HVAC, 20 is the minimum for ConductionFiniteDifference and HeatAndMoistureFiniteElement simulations. Green roof (ref: **Material:RoofVegetation**) also may require more timesteps.

Note that hourly data (such as outdoor conditions expressed by Design Days or Weather data) are interpolated to the Zone Timestep. This is discussed in a later section: Weather Data Hourly Interpolation

### 1.5.3 ConvergenceLimits

This item is an “advanced” feature that should be used only with caution. It is specifically included to assist some users “speed up” calculations while not overly compromising accuracy. The user

must judge for him/herself whether the reduced run time is useful.

### 1.5.3.1 Inputs

#### 1.5.3.1.1 Field: Minimum System Timestep

Usually the minimum system timestep is allowed to vary from the zone timestep (as maximum) to a minimum timestep of 1 minute during certain system calculations. This might be when the system turns on or off, for example. Entering 0 in this field sets the minimum system timestep to be the same as the zone timestep. Otherwise the units of the field are minutes. It's probably a good idea to have any minimum entered be a divisor of the zone timestep.

#### 1.5.3.1.2 Field: Maximum HVAC Iterations

The HVAC Manager will iterate to a solution or up to a set number of iterations. If not “converged”, then a warning error appears:

```
SimHVAC: Maximum iterations (20) exceeded for all HVAC loops, at CHICAGO IL USA TMY2-94846 WMO# = 725300,
10/07 14:06 - 14:08
```

In order to reduce time used in simulating your building, you may choose to enter a lesser number than the default of 20 for the maximum number of iterations to be used. Or, you may wish to enter a bigger number for certain buildings. To get more information printed with a “max iteration” message, you need to enter a “[Output:Diagnostics](#), `DisplayExtraWarnings`;” command (which may also generate other warnings than just this one).

#### 1.5.3.1.3 Field: Minimum Plant Iterations

The plant system modeling includes a solver that iterates within a single HVAC manager iteration. This input field and the next one provide some control over how the plant solver iterates. This field sets a minimum threshold for plant iterations. The default for this field is the value “2” which indicates that a minimum of two full plant model iterations will be performed every time plant is called by the HVAC manager. For faster performance with simple plant systems, this input field could be set to the value “1”. For complicated plant systems that present difficulties to solve, this value may need to be set higher to ensure accuracy but at the expense of speed. Complicated plant systems include those with several interconnected loops, sizing miss-matches such that plant components are starved of flow compared to their desired flow, heat recovery systems, and thermal load following onsite generators.

#### 1.5.3.1.4 Field: Maximum Plant Iterations

The plant system solver iterates within a single HVAC manager iteration. This input field and the previous one provide some control over how the plant model iterates. This field sets a maximum limit for plant iterations. The default for this field is the value “8” which indicates that the plant solver will exit after having completed eight full iterations. This value can be raised for better accuracy with complex plants or lowered for faster speed with simple plants. The output variable called “Plant Solver Sub Iteration Count” (typically reported at the “detailed” frequency) is useful for understanding how many plant solver iterations are actually being used during a particular simulation. The lower limit of the value for this field is “2.”

Use in an IDF:

```

ConvergenceLimits,
0,          !- Minimum System Timestep (0 = same as zone timestep)
25,         !- Maximum HVAC Iterations
3,          !- Minimum Plant Iterations
9;          !- Maximum Plant Iterations

```

---

## 1.5.4 Building

The Building object describes parameters that are used during the simulation of the building. There are necessary correlations between the entries for this object and some entries in the [Site:WeatherStation](#) and [Site:HeightVariation](#) objects, specifically the Terrain field.

### 1.5.4.1 Inputs

#### 1.5.4.1.1 Field: Building Name

Building name is specified for output convenience.

#### 1.5.4.1.2 Field: North Axis

The Building North Axis is specified **relative to true North**. Buildings frequently do not line up with true north. For convenience, one may enter surfaces in a “regular” coordinate system and then shift them via the use of the North Axis. The value is specified in degrees from “true north” (clockwise is positive).

The figure below shows how the building north axis can be rotated to correspond with one of the major axes of an actual building. The relevance of this field is described more completely under “[GlobalGeometryRules](#)”; in particular, the value of “North Axis” is *ignored* if a coordinate system other than “relative” is used.

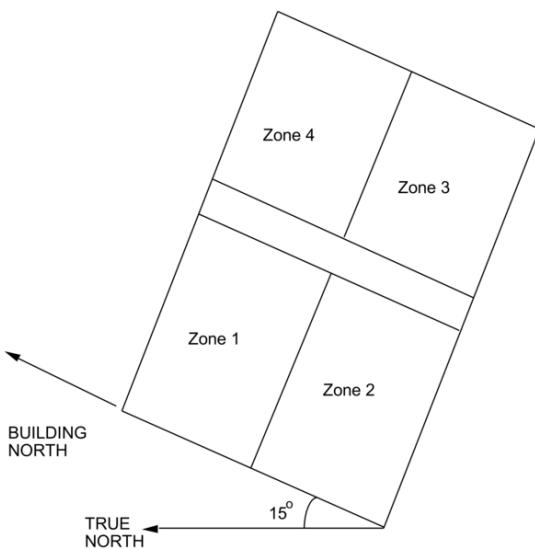

Figure 1.1: Illustration of Building North Axis

#### 1.5.4.1.3 Field: Terrain

The site's terrain affects how the wind hits the building – as does the building height. In addition, the external conduction method usually has its own parameters for the calculation. Please see the Engineering Documentation, External Conduction section for particulars. The legal values for this field are shown in the following table.

Table 1.2: Values for “Terrain”

Terrain Type	Value	Terrain Description
Country		Flat, Open Country
Suburbs		Rough, Wooded Country, Suburbs
City		Towns, city outskirts, center of large cities
Ocean		Ocean, Bayou flat country
Urban		Urban, Industrial, Forest

#### 1.5.4.1.4 Warmup Convergence

The following two fields along with the minimum and maximum number of warmup days (also in this object) define the user specified criteria for when EnergyPlus will “converge” at each environment (each sizing period or run period set as Yes in the [SimulationControl](#) object). At the beginning of a new environment the building model is reinitialized so that temperatures are initialized to 23C and zone humidity ratios are initialized to the outdoor humidity ratio (unless this initialization is suppressed using the input field called Begin Environment Reset Mode in the [SizingPeriod:DesignDay](#) object). EnergyPlus repeatedly “runs” the first day of the environment or until it reaches “maximum number of warmup days” or the convergence criteria are met. Note that setting the convergence tolerance values too loose will cause the program to be satisfied too early and you may not get the results you expect from the actual simulation. However too tight of a value and the program will repeat the first day too many times leading to excessive simulation run time.

#### 1.5.4.1.5 Field: Loads Convergence Tolerance Value

This value represents the number at which the loads values must agree before “convergence” is reached. Loads tolerance is the change in peak zone heating and cooling loads that are predicted from previous warmup day to the current day, in units of W.

#### 1.5.4.1.6 Field: Temperature Convergence Tolerance Value

This value represents the number at which the zone temperatures must agree (from previous iteration) before “convergence” is reached. (Units for this field is delta C).

Convergence of the simultaneous heat balance/HVAC solution is reached when either the loads or temperature criterion is satisfied.

All tolerances have units so the temperature tolerance is in degrees C (or degrees K) and the loads tolerance is in Watts. Both tolerances work the same way, just one looks at temperatures and one looks at heating and cooling loads. After the second warm-up day, the program compares the maximum temperature experienced in a space with the maximum temperature from the previous day. If those two temperatures are within the tolerance, then it has passed the first warm-up check.

It does a similar comparison with lowest temperatures experience within all the zones. If the current simulation day and the previous day values are within the tolerance, then it has passed the second warm-up check. Similar things are done with the loads tolerance and the maximum heating and cooling loads that are experienced within the spaces. Those are compared individually to the values for the previous day. If they are both in tolerance, then the simulation has passed the third and fourth warm-up check. The simulation stays in the warm-up period until ALL FOUR checks have been passed. See Engineering Reference and Output Details document for further explanation and outputs.

Please note—other “convergence tolerance” inputs are required for certain HVAC equipment (unit ventilator, unit heater, window AC, etc.). The purpose and units of these parameters are different from “load convergence tolerance” and “temperature convergence tolerance” in the BUILDING object.

#### 1.5.4.1.7 Field: Solar Distribution

Setting this value determines how EnergyPlus treats beam solar radiation and reflectances from exterior surfaces that strike the building and, ultimately, enter the zone. There are five choices: **MinimalShadowing**, **FullExterior** and **FullInteriorAndExterior**, **FullExteriorWithReflections**, **FullInteriorAndExteriorWithReflections**.

##### **MinimalShadowing**

In this case, there is no exterior shadowing except from window and door reveals. All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor’s solar absorptance. Any reflected by the floor is added to the reflected diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone’s air with the absorbed radiation being treated as a flux on the surface.

##### **FullExterior, FullExteriorWithReflections**

In this case, shadow patterns on exterior surfaces caused by detached shading, wings, overhangs, and exterior surfaces of all zones are computed. As for MinimalShadowing, shadowing by window and door reveals is also calculated. Beam solar radiation entering the zone is treated as for MinimalShadowing – All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor’s solar absorptance. Any reflected by the floor is added to the reflected diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone’s air with the absorbed radiation being treated as a flux on the surface.

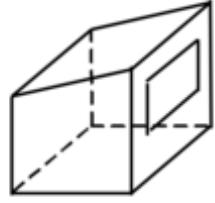

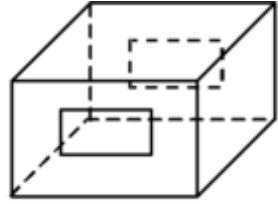

##### **FullInteriorAndExterior, FullInteriorAndExteriorWithReflections**

This is the same as FullExterior except that instead of assuming all transmitted beam solar falls on the floor the program calculates the amount of beam radiation falling on each surface in the zone, including floor, walls and windows, by projecting the sun’s rays through the exterior windows, taking into account the effect of exterior shadowing surfaces and window shading devices.

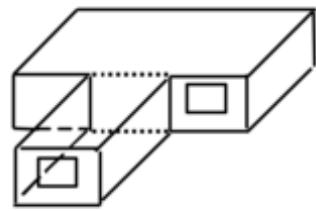

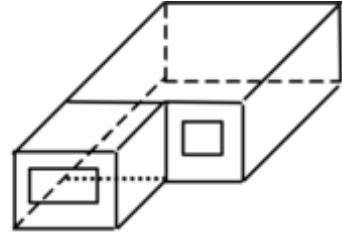

If this option is used, you should be sure that the surfaces of the zone totally enclose a space. This can be determined by viewing the **eplusout.dxf** file with a program like AutoDesk’s Volo View Express. You should also be sure that the zone is **convex**. Examples of convex and non-convex zones are shown in Figure 1.2. The most common non-convex zone is an L-shaped zone. (A formal definition of convex is that any straight line passing through the zone intercepts at most

two surfaces.) If the zone's surfaces do not enclose a space or if the zone is not convex you should use Solar Distribution = **FullExterior** instead of **FullInteriorAndExterior**.

If you use **FullInteriorAndExterior** the program will also calculate how much beam radiation falling on the inside of an exterior window (from other windows in the zone) is absorbed by the window, how much is reflected back into the zone, and how much is transmitted to the outside. In this calculation the effect of a shading device, if present, is accounted for.

**Convex zones**

**Non-Convex zones**

Figure 1.2: Illustration of Convex and Non-convex Zones

### Diffuse Radiation

Diffuse solar transmitted through exterior and interior windows is distributed according to the approximate view factors between the transmitting window and all other heat transfer surfaces in the zone. The portion of this diffuse solar that is reflected by all surfaces in the zone is subsequently redistributed uniformly (based on area and solar absorptance) to all heat transfer surfaces in the zone, along with interior reflected beam solar and shortwave radiation from lights. Refer to the section “Solar Distribution” in the Engineering Reference Guide for more information including equations.

### Reflection calculations

Note: Using the reflection calculations can be very time-consuming. Even error-prone. As a possible alleviation, you can use the **Output:Diagnostics** “**DoNotMirrorDetachedShading**” in many cases to get past a fatal error.

If using reflections, the program calculates beam and sky solar radiation that is reflected from exterior surfaces and then strikes the building. These reflecting surfaces fall into three categories:

1) **Shadowing surfaces.** These are surfaces like overhangs or neighboring buildings entered with Shading:Site, Shading:Building, Shading:Site:Detailed, Shading:Building:Detailed, Shading:Overhang, Shading:Overhang:Projection, Shading:Fin, Shading:Fin:Projection or Shading:Zone:Detailed objects. See Figure 1.3.

These surfaces can have diffuse and/or specular (beam-to-beam) reflectance values that are specified with the ShadingProperty:Reflectance object which specifies those parameters. They have a default value of .2 for both visible and diffuse reflection.

2) **Exterior building surfaces.** In this case one section of the building reflects solar radiation onto another section (and vice-versa). See Figure 1.4.

The building surfaces are assumed to be diffusely reflecting if they are opaque (walls, for example) and specularly reflecting if they are windows or glass doors. The reflectance values for opaque surfaces are calculated by the program from the Solar Absorptance and Visible Absorptance values of the outer material layer of the surface's construction (ref: Material object properties). The reflectance values for windows and glass doors are calculated by the program from the reflectance properties of the individual glass layers that make up surface's construction assuming no shading device is present and taking into account inter-reflections among the layers (ref: Window Properties).

3) **The ground surface.** Reflection from the ground is calculated even if reflections option is not used; but then the ground plane is considered unobstructed, i.e., the shadowing of the ground by the building itself or by obstructions such as neighboring buildings is ignored. Shadowing by the building itself or neighboring buildings is taken into account when the “with reflections” option is used but then the “view factor to ground” is NOT used. This is shown in Figure 1.5.

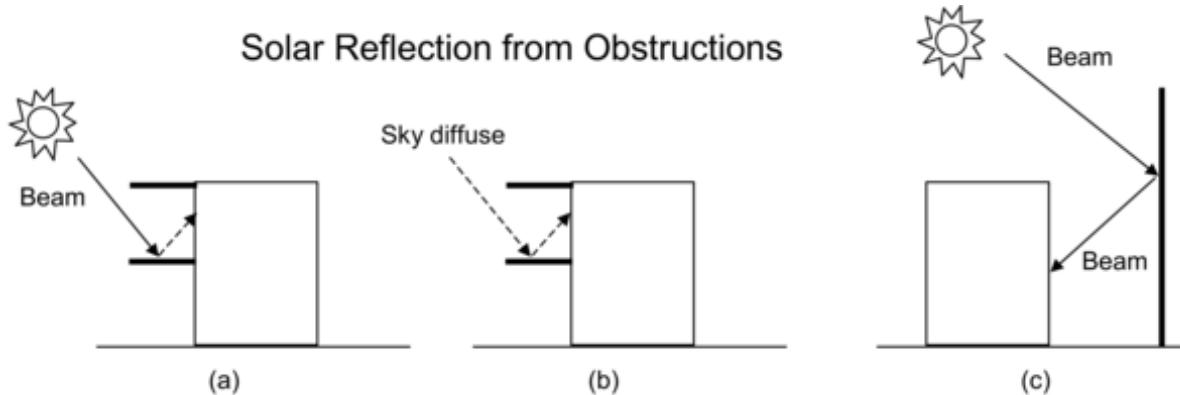

Figure 1.3: Solar reflection from shadowing surfaces. Solid arrows are beam solar radiation; dashed arrows are diffuse solar radiation. (a) Diffuse reflection of beam solar radiation from the top of an overhang. (b) Diffuse reflection of sky solar radiation from the top of an overhang. (c) Beam-to-beam (specular) reflection from the façade of an adjacent highly-glazed building represented by a vertical shadowing surface.

#### 1.5.4.1.8 Field: Maximum Number of Warmup Days

This field specifies the number of “warmup” days that might be used in the simulation before “convergence” is achieved. The default number, 25, is usually more than sufficient for this task; however, some complex buildings (with complex constructions) may require more days. If you enter less than 25 as a maximum, that is the number of maximum warmup days that will be used. An error message will occur when the simulation “runs” out of days and has not converged:

```
CheckWarmupConvergence: Loads Initialization, Zone = "MAIN ZONE" did not converge after 30 warmup days.
See Warmup Convergence Information in .eio file for details
..Environment(SizingPeriod) = "DENVER CENTENNIAL GOLDEN N ANN CLG 1% CONDNS DB = >MWB"
```

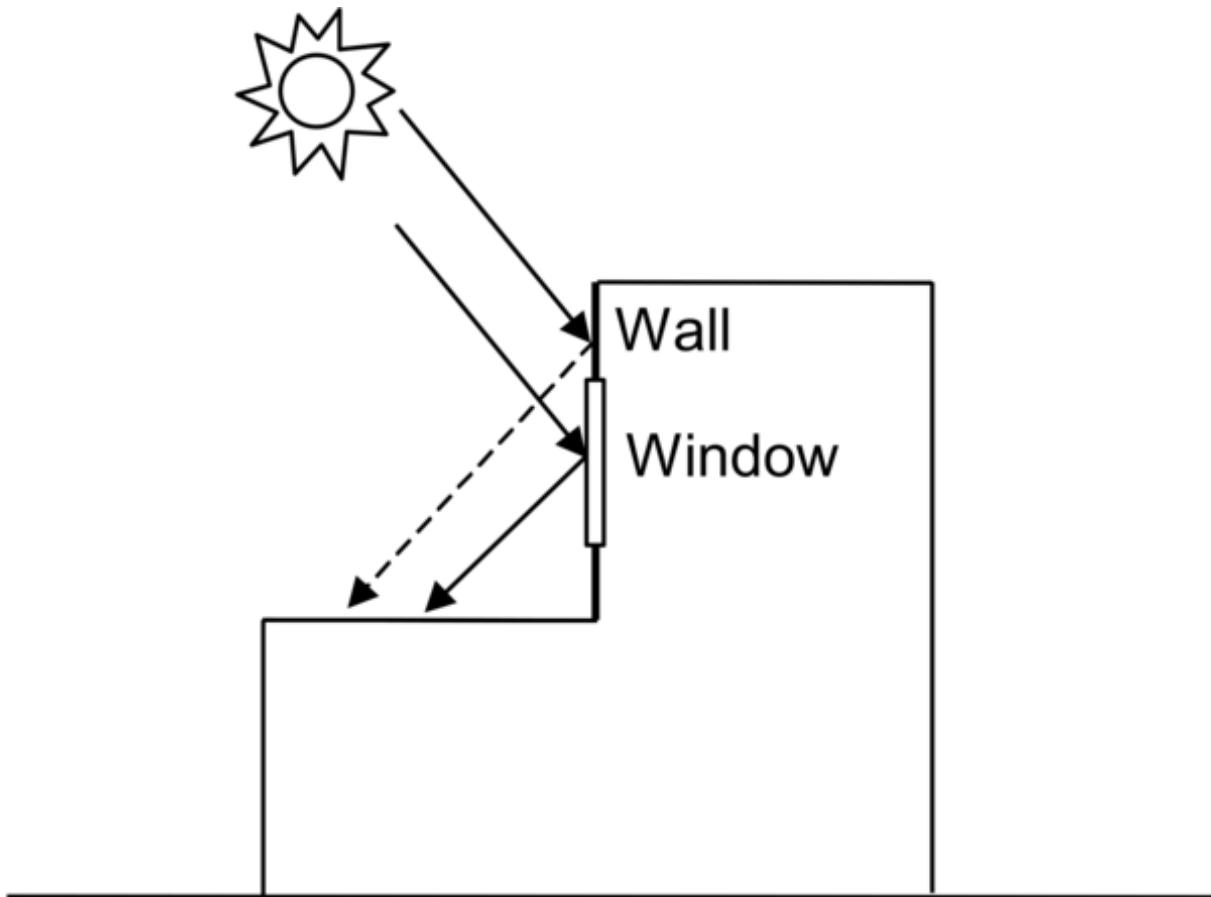

Figure 1.4: Solar reflection from building surfaces onto other building surfaces. In this example beam solar reflects from a vertical section of the building onto a roof section. The reflection from the window is specular. The reflection from the wall is diffuse.

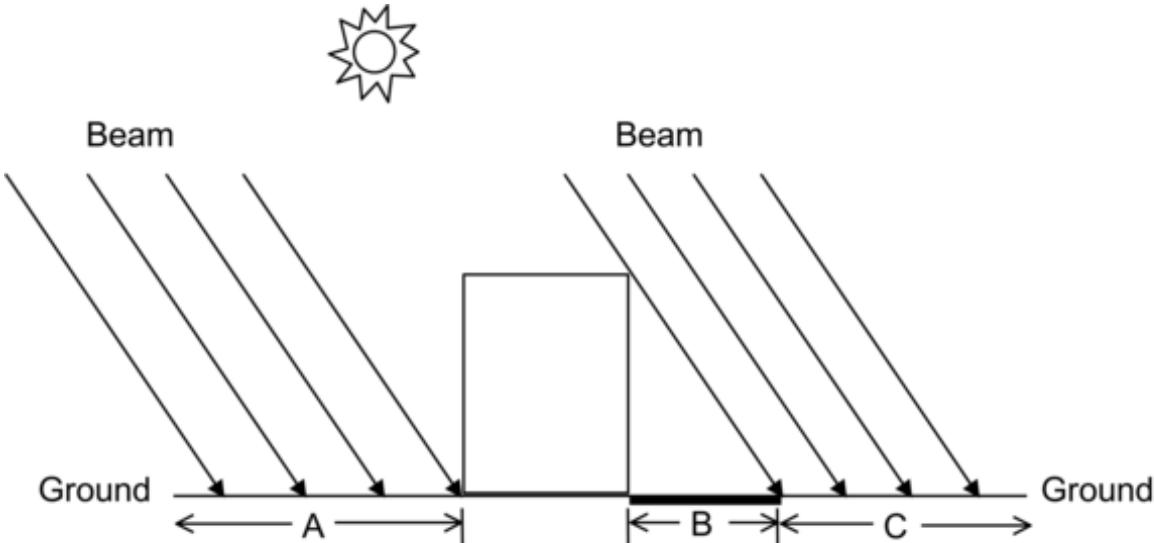

Figure 1.5: Shadowing from building affects beam solar reflection from the ground. Beam-to-diffuse reflection from the ground onto the building occurs only for sunlit areas, A and C, not from shaded area, B.

```
..Max Temp Comparison = 2.06E-002 vs Temperature Convergence Tolerance = 0.50 - Pass Convergence
..Min Temp Comparison = 5.95E-003 vs Temperature Convergence Tolerance = 0.50 - Pass Convergence
..Max Cool Load Comparison = 9.5082E-002 vs Loads Convergence Tolerance = 5.00E-002 - Fail Convergence
```

As noted in the message, there will be more information in the .eio file. (Refer to Output Details document as well for examples.)

You may be able to increase the Maximum Number of Warmup Days and get convergence, but some anomalous buildings may still not converge. Simulation proceeds for x warmup days until “convergence” is reached (see the discussion under the Temperature Convergence Tolerance Value field in this object, just above).

The value in this field is an overall parameter for all types of environments in the simulation. The maximum nmber of warmup days can also be controlled separately for individual designdays using the input field Maximum Number Warmup Days in the [SizingPeriod:DesignDay](#) object.

#### 1.5.4.1.9 Field: Minimum Number of Warmup Days

This field specifies the minimum number of “warmup” days before EnergyPlus will check if it has achieved convergence and can thus start simulating the particular environment (design day, annual run) in question. Although some older investigations indicated that 6 warmup days is generally enough on the minimum end of the spectrum, current thinking is that the convergence checks (controlled by convergence tolerance values above) can be relied on to determine a minimum number of warm days. An arbitrary high minimum can lead to excessive run times for lightweight buildings that may converge quickly and not need many warmup days. Therefore the default is reduced from 6 to just 1. A value of 6 here will replicate older behavior if field was being left blank. Users may wish to increase the value in certain situations when, based on the output variables described in the Output Details document, it is determined that EnergyPlus has not converged. While this parameter should be less than the previous maximum parameter, a value greater than the value entered in the field “Maximum Number of Warmup Days” above may be used when users

wish to increase warmup days more than the previous field. In this particular case, the previous field will be automatically reset to the value entered in this field and EnergyPlus will run exactly the number of warmup days specified in this field.

An example from an IDF:

```
Building,
  PSI HOUSE DORM AND OFFICES, !- Name
  36.87000,           !- North Axis {deg}
  Suburbs,            !- Terrain
  0.04,               !- Loads Convergence Tolerance Value
  0.4000000,          !- Temperature Convergence Tolerance Value {deltac}
  FullInteriorAndExterior, !- Solar Distribution
  40,                 !- Maximum Number of Warmup Days
  6;                  !- Minimum Number of Warmup Days
```

## 1.5.5 SurfaceConvectionAlgorithm:Inside

This input object is used control the choice of models used for surface convection at the inside face of all the heat transfer surfaces in the model. This object sets the selection for convection correlations in a global way. The Zone Inside Convection Algorithm input field in the Zone object may be used to selectively override this value on a zone-by-zone basis. Further, individual surfaces can refine the choice by each surface or surface lists – see object [SurfaceProperty:ConvectionCoefficients](#) and object [SurfaceProperty:ConvectionCoefficients:MultipleSurface](#).

### 1.5.5.1 Inputs

#### 1.5.5.1.1 Field: Algorithm

The model specified in this field is the default algorithm for the inside face all the surfaces.. The key choices are **Simple**, **TARP**, **CeilingDiffuser**, **AdaptiveConvectionAlgorithm**, and **ASTMC1340**.

The **Simple** model applies constant heat transfer coefficients depending on the surface orientation.

The **TARP** model correlates the heat transfer coefficient to the temperature difference for various orientations. This model is based on flat plate experiments.

The **CeilingDiffuser** model is a mixed and forced convection model for ceiling diffuser configurations. The model correlates the heat transfer coefficient to the air change rate for ceilings, walls and floors. These correlations are based on experiments performed in an isothermal room with a cold ceiling jet. To avoid discontinuities in surface heat transfer rate calculations, all of correlations have been extrapolated beyond the lower limit of the data set (3 ACH) to a natural convection limit that is applied during the hours when the system is off.

The **AdaptiveConvectionAlgorithm** model is an dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the [SurfaceConvectionAlgorithm:Inside:AdaptiveM](#) input object. These models are explained in detail in the EnergyPlus Engineering Reference Document.

The **ASTMC1340** model correlates mixed convection coefficients to the surface-to-air temperature difference, heat flow direction, surface tilt angle, surface characteristic length, and air speed past the surface. These correlations are based on ASTM C1340 standard.

The default is **TARP**.

IDF Example:

```
SurfaceConvectionAlgorithm:Inside , TARP ;
```

## 1.5.6 SurfaceConvectionAlgorithm:Outside

Various exterior convection models may be selected for global use. The optional Zone Outside Convection Algorithm input field in the Zone object may be used to selectively override this value on a zone-by-zone basis. Further, individual surfaces can refine the choice by each surface or surface lists – see object [SurfaceProperty:ConvectionCoefficients](#) and object [SurfaceProperty:ConvectionCoefficients:MultipleSurface](#).

### 1.5.6.1 Inputs

#### 1.5.6.1.1 Field: Algorithm

The available key choices are **SimpleCombined**, **TARP**, **MoWiTT**, **DOE-2**, and **AdaptiveConvectionAlgorithm**.

The **Simple** convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1.143, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals. Note that if **Simple** is chosen here or in the Zone field and a [SurfaceProperty:ConvectionCoefficients](#) object attempts to override the calculation with a different choice, the action will still be one of combined calculation. To change this, you must select one of the other methods for the global default.

All other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building’s location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program.

The **TARP** algorithm was developed for the TARP software and combines natural and wind-driven convection correlations from laboratory measurements on flat plates.

The **DOE-2** and **MoWiTT** were derived from field measurements. DOE-2 uses a correlation from measurements by Klems and Yazdanian for rough surfaces. MoWitt uses a correlation from measurements by Klems and Yazdanian for smooth surfaces and, therefore, is most appropriate for windows (see [SurfaceProperty:ConvectionCoefficients:MultipleSurface](#) for how to apply to only windows).

The **AdaptiveConvectionAlgorithm** model is an dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the [SurfaceConvectionAlgorithm:Outside:Adaptive](#) input object. All algorithms are described more fully in the Engineering Reference.

The default is **DOE-2**.

Note that when the surface is wet (i.e. it is raining and the surface is exposed to wind) then the convection coefficient appears as a very large number (1000) and the surface is exposed to the Outdoor Wet-bulb Temperature rather than the Outdoor Dry-bulb Temperature.

IDF Example:

```
SurfaceConvectionAlgorithm:Outside , AdaptiveConvectionAlgorithm ;
```

## 1.5.7 HeatBalanceAlgorithm

The HeatBalanceAlgorithm object provides a way to select what type of heat and moisture transfer algorithm will be used for calculating the performance of the building's surface assemblies. This input controls the overall algorithm used for all the surfaces unless one or more of the SurfaceProperty:HeatTransferAlgorithm:<sup>\*</sup> objects are used to alter the selection for particular surfaces.

### 1.5.7.1 Inputs

#### 1.5.7.1.1 Field: Algorithm

Four values are allowed to select which solution will be used.

- The **ConductionTransferFunction** selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements.
- The **MoisturePenetrationDepthConductionTransferFunction** selection is a sensible heat diffusion and an inside surface moisture storage algorithm that also needs additional moisture material property information. Sometimes, this is referred to as the Effective Moisture Penetration Depth or EMPD. See the moisture material property object for additional information and description of outputs:
  - [MaterialProperty:MoisturePenetrationDepth:Settings](#)
- **Advanced/Research usage:** The **ConductionFiniteDifference** selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements. This solution technique uses a 1-D finite difference solution in the construction elements. Outputs for the surfaces are described with the material property objects. The Conduction Finite Difference (aka CondFD) property objects are:
  - [MaterialProperty:PhaseChange](#)
  - [MaterialProperty:VariableThermalConductivity](#)
  - [MaterialProperty:PhaseChangeHysteresis](#)
- **Advanced/Research usage:** The **CombinedHeatAndMoistureFiniteElement** is a coupled heat and moisture transfer and storage solution. The solution technique uses a one dimensional finite difference solution in the construction elements and requires further material properties described in the Heat and Moisture Transfer material properties objects. Outputs from the algorithm are described with these objects. The Heat and Moisture Transfer property objects are:
  - [MaterialProperty:HeatAndMoistureTransfer:Settings](#)
  - [MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm](#)
  - [MaterialProperty:HeatAndMoistureTransfer:Suction](#)
  - [MaterialProperty:HeatAndMoistureTransfer:Redistribution](#)
  - [MaterialProperty:HeatAndMoistureTransfer:Diffusion](#)
  - [MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity](#)

### 1.5.7.1.2 Field: Surface Temperature Upper Limit

This field is a bit “advanced”. It should only be used when the simulation fails AND you cannot determine a cause for the failure. That is, you receive an error similar to:

```
** Severe ** Temperature out of bounds (202.91) for surface = Wall1
**   ~~~ ** in Zone = Zone01
**   ~~~ ** Occurrence info = NEW YORK CITY NY SUMMER, 07/21 16:00 - 16:01
**   ~~~ ** A temperature out of bounds problem can be caused by several things. The user
**   ~~~ ** should check the weather environment, the level of internal gains with respect
**   ~~~ ** to the zone, and the thermal properties of their materials among other things.
**   ~~~ ** A common cause is a building with no thermal mass -- all materials with
**   ~~~ ** Regular-R definitions.
```

And, after careful perusal, you cannot find a solution as suggested in the error description. You may then want to enter a higher number than the default for this field.

### 1.5.7.1.3 Field: Minimum Surface Convection Heat Transfer Coefficient Value

This optional field is used to set an overall minimum for the value of the coefficient for surface convection heat transfer ( $H_c$ ) in W/m<sup>2</sup>-K. A minimum is necessary for numerical robustness because some correlations for  $H_c$  can result in zero values and create numerical problems. This field can be used to support specialized validation testing to suppress convection heat transfer and to investigate the implications of different minimum  $H_c$  values. The default is 0.1.

### 1.5.7.1.4 Field: Maximum Surface Convection Heat Transfer Coefficient Value

This optional field is used to set an overall maximum for the value of the coefficient for surface convection heat transfer ( $H_c$ ) in W/m<sup>2</sup>-K. High  $H_c$  values are used in EnergyPlus to approximate fixed surface temperature boundary conditions. This field can be used to alter the accepted range of user-defined  $H_c$  values.

And, a default IDF example

```
HeatBalanceAlgorithm,ConductionTransferFunction; ! Solution Algorithm
```

## 1.5.8 HeatBalanceSettings:ConductionFiniteDifference

This object is used to control the behavior of the Conduction Finite Difference algorithm for surface heat transfer. The settings are global and affect how the model behaves for all the surfaces.

### 1.5.8.1 Inputs

#### 1.5.8.1.1 Field: Difference Scheme

This field determines the solution scheme used by the Conduction Finite Difference model. There are two options CrankNicholsonSecondOrder and FullyImplicitFirstOrder. The CrankNicholsonSecondOrder scheme is second order in time and may be faster. But it can be unstable over time when boundary conditions change abruptly and severely. The FullyImplicitFirstOrder scheme is first order in time and is more stable over time. But it may be slower. The default is FullyImplicitFirstOrder when ConductionFiniteDifference is selected as the Heat Balance Algorithm.

### 1.5.8.1.2 Field: Space Discretization Constant

This field controls how the model determines spatial discretization, or the count of nodes across each material layer in the construction. The model calculates the nominal distance associated with a node,  $\Delta x$ , using

$$\Delta x = \sqrt{C\alpha\Delta t} \quad (1.1)$$

Where

$\alpha$  is the thermal diffusivity of the material layer, in  $\text{m}^2/\text{s}$

$\Delta t$  is the length of the timestep in seconds.

$C$  is a constant set by this field.

The default is 3. Typical values are from 1 to 3. Lower values for this constant lead to more nodes and finer-grained space discretization.

### 1.5.8.1.3 Field: Relaxation Factor

The finite difference solver includes under-relaxation for improved stability for interactions with the other surfaces. This input field can optionally be used to modify the starting value for the relaxation factor. Larger numbers may solve faster, while smaller numbers may be more stable. The default is 1.0. If the program detects numerical instability, it may reduce the value entered here to something lower and more stable.

### 1.5.8.1.4 Field: Inside Face Surface Temperature Convergence Criteria

The surface heat balance model at the inside face has a numerical solver that uses a convergence parameter for a maximum allowable differences in surface temperature. This field can optionally be used to modify this convergence criteria. The default value is 0.002 and was selected for stability. Lower values may further increase stability at the expense of longer runtimes, while higher values may decrease runtimes but lead to possible instabilities. The units are in degrees Celsius.

An example IDF object follows.

```
HeatBalanceSettings:ConductionFiniteDifference,
  FullyImplicitFirstOrder, !- Difference Scheme
  3.0,                      !- Space Discretization Constant
  1.0,                      !- Relaxation Factor
  0.002;                    !- Inside Face Surface Temperature Convergence Criteria
```

## 1.5.9 ZoneAirHeatBalanceAlgorithm

The ZoneAirHeatBalanceAlgorithm object provides a way to select what type of solution algorithm will be used to calculate zone air temperatures and humidity ratios. This object is an optional object. If the default algorithm is used, this object is not required in an input file.

### 1.5.9.1 Inputs

#### 1.5.9.1.1 Field: Algorithm

Three choices are allowed to select which solution algorithm will be used. The ThirdOrderBackwardDifference selection is the default selection and uses the third order finite difference approximation to solve the zone air energy and moisture balance equations. The AnalyticalSolution selection uses the integration approach to solve the zone air energy and moisture balance equations. The

**EulerMethod** selection uses the first order finite backward difference approximation to solve the zone air energy and moisture balance equations.

And, a default IDF example is shown below:

```
ZoneAirHeatBalanceAlgorithm, ThirdOrderBackwardDifference; !- Algorithm
```

## 1.5.10 ZoneAirContaminantBalance

The ZoneAirContaminantBalance object provides a way to select which contaminant type will be simulated. Although carbon dioxide is not considered as an indoor contaminant but it is used as an indicator of indoor air quality in buildings. From modeling point of view EnergyPlus treats carbon dioxide as a type of contaminant. In addition to carbon dioxide, a generic contaminant type model was also added. This object is optional, only required in the input data file if the user wishes to model contaminant concentration levels as part of their simulation.

### 1.5.10.1 Inputs

#### 1.5.10.1.1 Field: Carbon Dioxide Concentration

Input is Yes or No. The default is No. If Yes, simulation of carbon dioxide concentration levels will be performed. If No, simulation of carbon dioxide concentration levels will not be performed.

#### 1.5.10.1.2 Field: Outdoor Carbon Dioxide Schedule Name

This field specifies the name of a schedule that contains outdoor air carbon dioxide level values in units of ppm. One source of monthly average CO<sub>2</sub> levels in the atmosphere is available at [NOAA's website](#) or via [ftp](#).

#### 1.5.10.1.3 Field: Generic Contaminant Concentration

Input is Yes or No. The default is No. If Yes, simulation of generic contaminant concentration levels will be performed. If No, simulation of generic contaminant concentration levels will not be performed.

#### 1.5.10.1.4 Field: Outdoor Generic Contaminant Schedule Name

This field specifies the name of a schedule that contains outdoor air generic contaminant level values in units of ppm.

An IDF example:

```
ZoneAirContaminantBalance,
  Yes,                               !- Carbon Dioxide Concentration
  Outdoor CO2 Schedule,           !- Outdoor Carbon Dioxide Schedule Name
  Yes,                               !- Generic Contaminant Concentration
  Generic Contaminant Schedule; !- Outdoor Generic Contaminant Schedule Name
```

### 1.5.10.2 Outputs

The following output variables are available when Carbon Dioxide Concentration = Yes.

```
HVAC,Average,Zone Air CO2 Internal Gain Volume Flow Rate [m3/s]
HVAC,Average,Zone Air CO2 Concentration [ppm]
```

### 1.5.10.2.1 Zone Air CO<sub>2</sub> Concentration [ppm]

This output variable represents the carbon dioxide concentration level in parts per million (ppm) for each zone. This is calculated and reported from the Correct step in the Zone Air Contaminant Predictor-Corrector module.

### 1.5.10.2.2 Zone Air CO<sub>2</sub> Internal Gain Volume Flow Rate [m<sup>3</sup>/s]

This is the total (net) rate of carbon dioxide internal gains/losses for a zone in m<sup>3</sup>/s from all types of sources or sinks. It includes impacts from three objects: ZoneContaminantSourceAndSink:CarbonDioxide, People, and GasEquipment. Positive values denote carbon dioxide generation (gain or source), while negative values denote carbon dioxide removal (loss or sink).

## 1.5.10.3 Outputs

The following output variable is available when Generic Contaminant Concentration = Yes.

HVAC,Average,Zone Generic Air Contaminant Generation Volume Flow Rate [m<sup>3</sup>/s]

HVAC,Average,Zone Air Generic Air Contaminant Concentration [ppm]

### 1.5.10.3.1 Zone Air Generic Air Contaminant Concentration [ppm]

This output variable represents the generic contaminant concentration level in parts per million (ppm) for each zone. This is calculated and reported from the Correct step in the Zone Air Contaminant Predictor-Corrector module.

### 1.5.10.3.2 Zone Generic Air Contaminant Generation Volume Flow Rate [m<sup>3</sup>/s]

This is the rate of generic air contaminant added (or subtracted) to a zone from all types of sources or sinks.

## 1.5.11 ShadowCalculation

This object is used to control some details of EnergyPlus's solar, shadowing and daylighting models. There are two basic methods available for the calculations. In order to speed up the calculations, shadowing calculations (sun position, etc.) for the default method are performed over a period of days. Note that this value may be very important for determining the amount of sun entering your building and by inference the amount of cooling or heating load needed for maintaining the building. Though termed "shadowing" calculations, it in affect determines the sun position for a particular day in a weather file period simulation. (Each design day will use the date of the design day object). Even though weather file data contains the amount of solar radiation, the internal calculation of sun position will govern how that affects various parts of the building. By default, the calculations are done for every 20 days throughout a weather run period; an average solar position is chosen and the solar factors (such as sunlit areas of surfaces) remain the same for that number of days. When more integrated calculations are needed for controlling dynamic windows or shades, a second method is available where solar calculations are performed at each zone timestep.

This object also allows setting up global flags to import and export exterior shading calculations results. This enables importing pre-calculated results of the shading fractions for each exterior building surface from external simulation tools. This also enables reusing the shading results for parametric runs which usually do not change external shading.

The object also allows input to disable self-shading effect from exterior surfaces from all zones, or from a subset of zones. Two flags are defined to enable the maximal flexibility of various interpretation of self-shading: one to disable shading between zones of a same zone group, the other to disable shading between different zone groups. The shading by exterior surfaces of the specified zones groups will be bypassed.

### 1.5.11.1 Inputs

#### 1.5.11.1.1 Field: Shading Calculation Method

Select between CPU-based polygon clipping method, the GPU-based pixel counting method, or importing from external shading data.

Choices are:

1. PolygonClipping
2. PixelCounting
3. Scheduled
4. Imported

Default: PolygonClipping

If **PixelCounting** is selected and GPU hardware (or GPU emulation) is not available, a warning will be displayed and EnergyPlus will revert to PolygonClipping. Unlike PolygonClipping, PixelCounting has no limitations related to zone concavity when used with any “FullInterior” solar distribution options (i.e., it can accommodate both concave and convex zones equally).

Use of the PixelCounting method requires some overhead in passing instructions between the CPU and the GPU. For low numbers of shading surfaces (less than about 200 for most hardware), PolygonClipping requires less runtime than PixelCounting. However, PixelCounting runtime scales significantly better at higher numbers of shading surfaces.

Some computers have multiple GPUs. In this case, the highest performance GPU is not always used by default. You may want to select which GPU is used when running EnergyPlus by setting the graphics performance preferences on your computer.

If **Scheduled** is chosen, the External Shading Fraction Schedule Name is required in **SurfaceProperty:LocalEnvironment**. If some exterior surfaces do not have their **SurfaceProperty:LocalEnvironment** objects, no shading is assigned on those exterior surfaces.

If **Imported** is chosen, the **Schedule:File:Shading** object is required to define the external file that stores all shading calculation results. The results are imported altogether by reading the **Schedule:File:Shading** object during initialization. The file explicitly defines the mappings to the surfaces. If the data for a surface is not listed in the file, no shading is assigned on this surface.

The sunlit fraction to overwrite accounts for the shading of both direct and sky diffuse solar radiation caused by all exterior shadowing surfaces. In this case, shadow patterns on exterior surfaces caused by detached shading, side-fins, overhangs, and exterior surfaces of all zones are overwritten. The interior shading devices, such as window shades and blinds, should be further calculated and applied after the importing.

### 1.5.11.1.2 Field: Shading Calculation Update Frequency Method

This field is used to control how the solar, shading, and daylighting models are calculated with respect to the time of calculations during the simulation. The default and fastest method is selected using the keyword Periodic. A more detailed and slower method can be selected using the keyword Timestep. The Timestep method must be used for modeling dynamic fenestration and shading surfaces.

### 1.5.11.1.3 Field: Shading Calculation Update Frequency

This numeric field will cause the shadowing calculations to be done periodically using the number in the field as the number of days in each period. This field is only used if the default Periodic calculation frequency method is used in the previous field. Using this field will allow you to synchronize the shadowing calculations with changes in shading devices. Using the default of 20 days in each period is the average number of days between significant changes in solar position angles. For these shadowing calculations, an “average” (over the time period) of solar angles, position, equation of time are also used.

### 1.5.11.1.4 Field: Maximum Figures in Shadow Overlap Calculations

This numeric field will allow you to increase the number of figures in shadow overlaps in the PolygonClipping method. Due to the shadowing algorithm, the number of shadows in a figure may grow quite large even with fairly reasonable looking structures. Of course, the inclusion of more allowed figures will increase calculation time. Likewise, too few figures may not result in as accurate calculations as you desire.

### 1.5.11.1.5 Field: Polygon Clipping Algorithm

This is an advanced feature. Prior to V7, the internal polygon clipping method was a special case of the Weiler-Atherton method. Now, three options are available:

**SutherlandHodgman** A simpler algorithm but it works well in cases where receiving surfaces (of shadows) are non-convex.

**ConvexWeilerAtherton** Only accurate where both casting and receiving surfaces are convex. Warnings/severe errors are displayed when necessary.

**SlaterBarskyandSutherlandHodgman** Slater-Barsky only applies to rectangular surfaces. Polygon clipping for rectangular surfaces will be calculated using the Slater-Barsky algorithm, while the rest adopts the default Sutherland-Hodgman algorithm.

Default is SutherlandHodgman. More details on polygon clipping are contained in the Engineering Reference.

### 1.5.11.1.6 Field: Pixel Counting Resolution

Number of pixels in both dimensions of the surface rendering. Higher resolution will create more accurate calculations, but can significantly increase computation time.

Default: 512.

#### 1.5.11.1.7 Field: Sky Diffuse Modeling Algorithm

Two choices are available here: SimpleSkyDiffuseModeling and DetailedSkyDiffuseModeling. **SimpleSkyDiffuseModeling** (default) performs a one-time calculation for sky diffuse properties. This has implications if you have shadowing surfaces with changing transmittance (i.e. not all opaque or not all transparent) during the year. The program checks to see if this might be the case and automatically selects **DetailedSkyDiffuseModeling** if the shading transmittance varies. Even if the transmittance doesn't vary and the option for detailed modeling is used, that option is retained (though it will increase execution time) because you may be using EMS to vary the transmittance. When the detailed modeling is done, there will be a warning posted if the Calculation Frequency (above) is > 1.

In general (and you should also read the previous field description), if shadowing surfaces are used with the transmittance property, the user should be careful to synchronize this calculation with the scheduled occurrence of the transmittance (if any) (or use 1, which will be the most accurate but will cause more time in the calculations).

This field applies to the shading calculation update frequency method called “Periodic.” When the method called “Timestep” is used the diffuse sky modeling always uses DetailedSkyDiffuseModeling.

**1.5.11.1.8 Field: Output External Shading Calculation Results** This fields indicates whether or not (**Yes** or **No**)to save internal shading calculation results to an external file, which can be imported back as needed. This file saves external sunlit fractions for all surfaces. If **Yes** is chosen, hourly shading fraction of all surfaces will be exported as a CSV file, naming as ”output file prefix + shading” (the default name is ”eplusshading.csv” if no output file prefix is defined). Each column of the CSV file lists the annually calculated shading fraction of each surface with time-step interval. It only writes data for each simulation day that shadows are calculated, e.g. once every 20 days by default. If the results are intended to be reused to be imported back using **ImportedShading** in **Field: External Shading Calculation Method**, the Calculation Frequency should be set as one to write year-round hourly results. Design days are not included. The default choice is **No**.

**1.5.11.1.9 Field: Disable Self-Shading Within Shading Zone Groups** This fields specifies during shading calculation, for all surfaces in a targeted Zone Group, whether or not (**Yes** or **No**) the self-shading effect by exterior surfaces of all zones within the target Zone Group is disabled. If Yes, self-shading will be disabled from all exterior surfaces in a given Shading Zone Group to surfaces within the same Shading Zone Group. If both Disable Self-Shading Within Shading Zone Groups and Disable Self-Shading From Shading Zone Groups to Other Zones = Yes, then all self-shading from exterior surfaces will be disabled. If only one of these fields = Yes, then at least one Shading Zone Group must be specified, or this field will be ignored. Shading from Shading:\* surfaces, overhangs, fins, and reveals will not be disabled.

#### 1.5.11.1.10 Field: Disable Self-Shading From Shading Zone Groups to Other Zones

This fields specifies during shading calculation, for all surfaces in a targeted Zone Group, whether or not (**Yes** or **No**) the self-shading effect from all exterior surfaces in the target Zone Group to other zones is disabled. If Yes, self-shading will be disabled from all exterior surfaces in a given Shading Zone Group to all other zones in the model. If both Disable Self-Shading Within Shading Zone Groups and Disable Self-Shading From Shading Zone Groups to Other Zones = Yes, then all

self-shading from exterior surfaces will be disabled. If only one of these fields = Yes, then at least one Shading Zone Group must be specified, or this field will be ignored. Shading from Shading:<sup>\*</sup> surfaces, overhangs, fins, and reveals will not be disabled.

**1.5.11.1.11 Field: Shading Zone Group ZoneList Name** The shading zones group specifies group of zones which are controlled by the Disable Self-Shading fields. This object is extensible, so additional fields of this type can be added to the end of this object.

Examples of this object in IDF: (note this object must be unique in an IDF)

```
ShadowCalculation, PixelCounting, Periodic, 1;
ShadowCalculation, PolygonClipping, Periodic, 1, , SutherlandHodgman, , DetailedSkyDiffuseModeling;
ShadowCalculation, Scheduled, Periodic, , , , Yes;
ShadowCalculation, PolygonClipping, Periodic, , , , , Yes, No, ShadingZoneGroup;
```

Note that the use of “1” in the examples is NOT the same as using Timestep calculation frequency – “1” causes daily calculation of the sun position variables but does not change the shadowing calculations more frequently than daily.

## 1.5.12 Output:Diagnostics

Sometimes, messages only confuse users – especially new users. Likewise, sometimes certain output variables exist for only a certain condition but some take them at face value/name. Some features may be very important but under certain instances cause problems. Thus, we have added the **diagnostic output** object to be able to turn on or off certain messages, variables, and features depending on conditions.

Both fields of the Output:Diagnostics command can accept all the applicable keys. More than one object may be entered.

### 1.5.12.1 Inputs

#### 1.5.12.1.1 Field: key1, key2

Allowable choices are:

**DisplayAllWarnings** – use this to get all warnings (except the developer warnings “DisplayZoneAirHeatBalanceOffBalance”). This key sets all other display warning values to on.

**DisplayExtraWarnings** – use this to get all extra warnings. An example of an extra warning is when a user enters a ceiling height or volume with the Zone object and EnergyPlus calculates something significantly different based on the entered zone geometry.

**DisplayUnusedSchedules** – use this to have the unused schedules (by name) listed at the end of the simulation.

**DisplayUnusedObjects** – use this to have unused (orphan) objects (by name) listed at the end of the simulation.

**DisplayAdvancedReportVariables** – use this to be able to use certain advanced output variables where the name may be misleading and you need to understand the concepts or reasons for use. If you put in this field, then you will be able to report on these features. They are noted in the descriptions of objects or output variables.

**DisplayZoneAirHeatBalanceOffBalance** – this is a developer diagnostic which you can turn on, if you desire.

**DoNotMirrorDetachedShading** – use this to turn off the automatic mirroring of detached shading surfaces. These surfaces are automatically mirrored so that the user does not need to worry about facing direction of the surface and the shading surface will shade the building as appropriate.

**DoNotMirrorAttachedShading** – use this to turn off the automatic mirroring of attached shading surfaces. These surfaces are automatically mirrored so that the user does not need to worry about facing direction of the surface and the shading surface will shade the building as appropriate. Attached shading surfaces include [Shading:Overhang](#), [Shading:Overhang:Projection](#), [Shading:Fin](#), [Shading:Fin:Projection](#), and [Shading:Zone:Detailed](#).

**DisplayWeatherMissingDataWarnings** – use this to turn on the missing data warnings from the read of the weather file.

**ReportDuringWarmup** – use this to allow reporting during warmup days. This can show you exactly how your facility is converging (or not) during the initial “warmup” days of the simulation. Generally, only developers or expert simulation users would need this kind of detail.

**ReportDetailedWarmupConvergence** – use this to produce detailed reporting (essentially each warmup day for each zone) for warmup convergence.

**ReportDuringHVACSizingSimulation** – use this to allow controlling reporting to SQLite database during sizing period simulations done for HVAC Sizing Simulation. The regular reporting is done in the usual way. This can show details of how advanced sizing adjustments were determined by documenting how the systems operated when doing the intermediate sizing periods. Depending on the number of iterations performed for HVAC Sizing Simulation, there will be a number of sets of results with each set containing all the Sizing Periods.

In IDF use:

```
Output:Diagnistics,  
DisplayExtraWarnings;
```

### 1.5.13 Output:DebuggingData

There may be times when a particular input file requires additional debugging. The Output:DebuggingData object may be used to report all available node data (e.g., temperature, mass flow rate, set point, pressure, etc.). The debug data is reported to the DBG text file. The debug file first reports the node number and name, and then all available node information for each zone time step (Ref. Timestep).

The 2 fields of the Output:DebuggingData object can accept either a 1 (turn on) or any other value (turn off). Only one object may be entered.

#### 1.5.13.1 Inputs

##### 1.5.13.1.1 Field: Report Debugging Data

This field turns on debug reporting when a value of 1 is entered. Any other value (usually 0) disables debug reporting.

##### 1.5.13.1.2 Field: Report During Warmup

This field allows the debug data to be reported during the warmup period. When a value of 1 is entered the data is reported at all times, even during warmup. Any other value (usually 0) disables “reporting at all time” and debug data is only reported for each environment ([RunPeriod](#) or [SizingPeriod:DesignDay](#)).

In IDF use:

```
Output:DebuggingData,
1,1;
```

---

## 1.5.14 Output:PreprocessorMessage

The Output:PreprocessorMessage object can be used by preprocessor programs to EnergyPlus for passing certain conditions/errors that might not be detected by scripts executing the EnergyPlus system of programs. This allows EnergyPlus to intercept problems and terminate gracefully rather than the user having to track down the exact conditions.

There is no reason for a user to enter an Output:PreprocessorMessage object but you should encourage interface developers to use this feature. More than one Output:PreprocessorMessage objects may be entered. Of course, no preprocessor message objects are necessary if there is no error information to be passed.

### 1.5.14.1 Inputs

#### 1.5.14.1.1 Field: Preprocessor Name

The preprocessor name (e.g. EPMacro, ExpandObjects) is entered here. Case is retained so that messages from EnergyPlus look very similar to what a preprocessor would produce.

#### 1.5.14.1.2 Field: Error Severity

This is the error severity. If Fatal, EnergyPlus will terminate after showing all preprocessor messages.

#### 1.5.14.1.3 Fields: Message Line 1 through Message Line 10

Each line is limited to 100 characters and an appropriate message can be composed.

An IDF Example:

```
Output:PreprocessorMessage,
No Preprocessor Used,      !- preprocessor name
Information,              !- error severity
Illustrative Message,     !- message line 1
No problems for processing; !- message line 2
```

---

And would appear in output:

```
Preprocessor = "No Preprocessor Used" has the following Information messages:
Illustrative Message
No problems for processing
```

---

## 1.5.15 ZoneCapacitanceMultiplier:ResearchSpecial

This object is an advanced feature that can be used to control the effective storage capacity of the zone. Capacitance multipliers of 1.0 indicate the capacitance is that of the (moist) air in the volume of the specified zone. This multiplier can be increased if the zone air capacitance needs to be increased for stability of the simulation or to allow modeling higher or lower levels of damping of behavior over time. The multipliers are applied to the base value corresponding to the total capacitance for the zone's volume of air at current zone (moist) conditions.

### 1.5.15.1 Inputs

#### 1.5.15.1.1 Field: Name

The name of the ZoneCapacitanceMultiplier:ResearchSpecial object.

#### 1.5.15.1.2 Field: Zone or ZoneList Name

This field is the name of the thermal zone (ref: Zone) and attaches a particular zone capacitance multiplier to a thermal zone or set of thermal zones in the building. When the **ZoneList** option is used then capacity multiplier is applied to each of the zones in the zone list.

#### 1.5.15.1.3 Field: Temperature Capacity Multiplier

This field is used to alter the effective heat capacitance of the zone air volume. This affects the transient calculations of zone air temperature. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the temperature of zone air from timestep to timestep. Note that sensible heat capacity can also be modeled using internal mass surfaces.

#### 1.5.15.1.4 Field: Humidity Capacity Multiplier

This field is used to alter the effective moisture capacitance of the zone air volume. This affects the transient calculations of zone air humidity ratio. Values greater than 1.0 have the effect of smoothing, or damping, the rate of change in the water content of zone air from timestep to timestep.

#### 1.5.15.1.5 Field: Carbon Dioxide Capacity Multiplier

This field is used to alter the effective carbon dioxide capacitance of the zone air volume. This affects the transient calculations of zone air carbon dioxide concentration. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the carbon dioxide level of zone air from timestep to timestep.

#### 1.5.15.1.6 Field: Generic Contaminant Capacity Multiplier

This field is used to alter the effective generic contaminant capacitance of the zone air volume. This affects the transient calculations of zone air generic contaminant concentration. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the generic contaminant level of zone air from timestep to timestep.

### 1.5.16 SimulationControl

The input for SimulationControl allows the user to specify what kind of calculations a given EnergyPlus simulation will perform. For instance the user may want to perform one or more of the sizing calculations but not proceed to an annual weather file simulation. Or the user might have all flow rates and equipment sizes already specified and desire an annual weather without any preceding sizing calculations. Sizing runs, even for large projects, are quickly run – they do not add much to the overall simulation time. The SimulationControl input allows all permutations of run selection by means of 5 yes/no inputs.

Only one SimulationControl object is permitted for each EnergyPlus input file. While a SimulationControl is needed to trigger sizing calculations, it is optional for other runs (design days, run periods). The actions will still be shown in the eplusout.eio file (see Output Details and Examples Document).

### 1.5.16.1 Inputs

#### 1.5.16.1.1 Field: Do Zone Sizing Calculation

Input is Yes or No. The default is No. Zone Sizing (see [Sizing:Zone](#) object) performs a special calculation, using a theoretical ideal zonal system, and determines the zone design heating and cooling flow rates and loads, saving the results in the zone sizing arrays.

#### 1.5.16.1.2 Field: Do System Sizing Calculation

Input is Yes or No. The default is No. System Sizing (see [Sizing:System](#) object) also performs a special calculation that, to oversimplify, sums up the results of the zone sizing calculation and saves the results in the system sizing arrays for reporting on component size requirements. Thus, in order to perform the system sizing calculations, the zone sizing arrays need to be filled and hence the zone sizing calculations must be performed in the same run. (This requirement is enforced by the program).

#### 1.5.16.1.3 Field: Do Plant Sizing Calculation

Input is Yes or No. The default is No. Unlike Zone and System Sizing, Plant Sizing does not use the Zone or System sizing arrays. Plant Sizing uses the [Sizing:Plant](#) object fields and data on the maximum component flow rates. The data on component (such as coil) flow rates is saved and made available to the Plant code whether or not component autosizing is performed and whether or not zone sizing and/or system sizing is performed. Therefore, you can specify Plant Sizing without also specifying to do Zone Sizing or System Sizing calculations.

#### 1.5.16.1.4 Field: Run Simulation for Sizing Periods

Input is Yes or No. The default is Yes. Yes implies that the simulation will be run on all the included SizingPeriod objects (i.e., SizingPeriod:DesignDay, SizingPeriod:WeatherFileDays, and SizingPeriod:WeatherFileConditionType). Note that each SizingPeriod object constitutes an “environment” and warmup convergence (see earlier topic under the Building object) will occur for each.

#### 1.5.16.1.5 Field: Run Simulation for Weather File Run Periods

Input is Yes or No. The default is Yes. Yes implies the simulation will be run on all the included [RunPeriod](#) objects. Note that each [RunPeriod](#) object constitutes an “environment” and warmup convergence (see earlier topic under the Building object) will occur for each.

#### 1.5.16.1.6 Field: Do HVAC Sizing Simulation for Sizing Periods

This field is optional. It can be used to enable certain advanced sizing calculations that rely on simulating the sizing periods to collect information. This is currently only applicable when sizing plant loops using the sizing option called Coincident.

### 1.5.16.1.7 Field: Maximum Number of HVAC Sizing Simulation Passes

This field is optional and is only used if the previous field is set to Yes. The HVAC Sizing Simulation approach can use iteration to improve sizing calculations. Each iteration is a Sizing Pass. This field is used to manually place an upper limit the number of passes that the sizing algorithms can use.

An IDF example:

```
SimulationControl,
No,           !- Do Zone Sizing Calculation
No,           !- Do System Sizing Calculation
No,           !- Do Plant Sizing Calculation
Yes,          !- Run Simulation for Sizing Periods
Yes,          !- Run Simulation for Weather File Run Periods
No,           !- Do HVAC Sizing Simulation for Sizing Periods
2;           !- Maximum Number of HVAC Sizing Simulation Passes
```

---

## 1.5.17 PerformancePrecisionTradeoffs

The PerformancePrecisionTradeoffs object can be used to control tradeoffs between performance (speed) and precision for certain EnergyPlus features. This object enables users to choose to use selected options that are intended to shorten the time needed for the computer to run EnergyPlus simulations, but may tend to decrease the accuracy of results compared to methods that require longer computing time. The field by field explanation of the object follows the next section, which describes the procedure by an example of how to use the `_perflog.csv` file in conjunction with the options available in the PerformancePrecisionTradeoffs object.

### 1.5.17.0.1 Tuning using the `_perflog.csv` file

Every time a simulation includes the PerformancePrecisionTradeoffs object, a file is generated with the same name as the input but ending with `_perflog.csv` file (the performance log file). This file can be opened using a spreadsheet program and may be helpful in adjusting the input field values for the PerformancePrecisionTradeoffs object. Unlike most EnergyPlus output files, a new line of results is appended (added to the end of the file) every time the input file is simulated. The `_perflog.csv` file contains a log of results from each run and allows the examination of the impacts of the changes to the PerformancePrecisionTradeoffs object and any other simulation inputs. You are encouraged to not make changes to any other portions of your input file other than the PerformancePrecisionTradeoffs object when you are tuning that object. Also, if you are looking at the `_perflog.csv` in a spreadsheet program, make sure you close the file before each simulation. A spreadsheet program will often lock a CSV file and prevent it from being modified by another program like EnergyPlus.

To illustrate how to use the PerformancePrecisionTradeoffs object and the `_perflog.csv` file together, here is an example using an IDF file with 100 zones, one window per zone, and is served by fan coil units and a central boiler and chiller. Seventeen simulations were made, and the results in the `<filename>_perflog.csv` for various options in the PerformancePrecisionTradeoffs object are shown below in the following tables.

Table 1.3: PerfLog Mode Columns

Run	Direct Coil	Radiant Algorithm	Override Mode	Num of Timesteps [#/hour]	Min Warmup	Suppress Resets	System Timestep [minute]	PsyTsatFnPb	MaxZone TempDiff	MaxAllowed DelTemp	Runtime [second]
1	FALSE	ScriptF	NORMAL	6	1	FALSE	1	Normal	0.30	0.002	275.56
2	FALSE	ScriptF	MODE01	1	1	FALSE	1	Normal	0.30	0.002	104.37
3	FALSE	ScriptF	MODE02	1	1	FALSE	1	Normal	0.30	0.002	98.81
4	FALSE	ScriptF	MODE03	1	1	FALSE	1	Normal	0.30	0.002	98.63
5	FALSE	ScriptF	MODE04	1	1	TRUE	1	Normal	0.30	0.002	97.87
6	FALSE	ScriptF	MODE05	1	1	TRUE	60	Normal	0.30	0.002	47.22
7	FALSE	ScriptF	MODE06	1	1	TRUE	60	Interpolate	0.30	0.002	45.48
8	FALSE	ScriptF	MODE07	1	1	TRUE	60	Interpolate	1.00	0.002	45.14
9	FALSE	ScriptF	MODE08	1	1	TRUE	60	Interpolate	1.00	0.1	44.18
10	TRUE	ScriptF	NORMAL	6	1	FALSE	1	Normal	0.30	0.002	273.42
11	FALSE	CarrollMRT	NORMAL	6	1	FALSE	1	Normal	0.30	0.002	276.68
12	FALSE	CarrollMRT	MODE01	1	1	FALSE	1	Normal	0.30	0.002	102.73
13	FALSE	CarrollMRT	MODE02	1	1	FALSE	1	Normal	0.30	0.002	97.28
14	FALSE	CarrollMRT	MODE03	1	1	FALSE	1	Normal	0.30	0.002	96.77
15	FALSE	CarrollMRT	MODE04	1	1	TRUE	1	Normal	0.30	0.002	96.56
16	FALSE	CarrollMRT	MODE05	1	1	TRUE	60	Normal	0.30	0.002	47.31
17	FALSE	CarrollMRT	MODE06	1	1	TRUE	60	Interpolate	0.30	0.002	45.62
18	FALSE	CarrollMRT	MODE07	1	1	TRUE	60	Interpolate	1.00	0.002	45.23
19	FALSE	CarrollMRT	MODE08	1	1	TRUE	60	Interpolate	1.00	0.1	44.09

This example uses 19 different simulations to arrive at the recommended values for the PerformancePrecisionTradeoffs object, but fewer trials could have been made to reach a similar conclusion. The first run (Run 1, Normal mode) shows the results of no performance precision tradeoffs being applied and is the same as not having the PerformancePrecisionTradeoffs object present. It is a good idea to use this as a first step so that a baseline of the time, errors, and oscillations are available for reference. Runs 2 through 9 are just stepping through the Override Modes (Mode01 to Mode08). Run 10 employs the “Use Coil Direct Solution” option, but the time gain for the simulation is not so significant. Therefore it is not used anymore in later runs. Runs 11 through 19 repeat the various override modes, but this time with the CarrollMRT radiant exchange algorithm. The biggest savings of the computation time are from Mode01 (Run 2) application. Compared to the Normal mode (Run 1) baseline, applying Mode01 (Run 2) immediately reduces the simulation time by 62%, to about only 37.9% of that for the Normal baseline. Then again, by applying Mode02 (Run 3), the simulation time is reduced by 5.3% compared to Mode02 (Run 1); Mode03 (Run 4) saves about 0.2% compared to Mode02 (Run 3); and Mode04 (Run 5) saves about 0.7% on top of Mode03 (Run 4). Compared to the normal baseline (Run 1), Mode04 (Run 5) only consumes about one third (35.5%) of the computation time of Run 1 Normal baseline.

Next, when Mode05 (Run 6) is applied, the simulation time is significantly reduced again—Mode05 reduces the simulation time by nearly a half compared to Mode04 (Run 5). The run time for Mode05 (Run 6) is only 51.8% of that for Mode04 (Run 5); and it is only 17.0% of the Normal baseline (Run 1). The run time for Mode06 (Run 7) was reduced by 3.7% in comparison with Mode05 (Run 6). Mode07 (Run 8) cuts the simulation time by about 0.7% compared to Mode06 (Run 7); the overall simulation time of Mode07 (Run 8) is about 16.4% of the Normal baseline. The final Mode08 (Run 9) cuts the simulation time by another 2.1% compared to Mode07 (Run 8); and the overall run time for Mode08 is only 16.0% (or about one-seventh) of that for the Run 1 Normal baseline.

In general, the higher models—Mode05 to Mode08—significantly save the simulation time

with both ScriptF and CarrollMRT, taking about one-fifth to one-seventh of the original Normal simulation time. These modes seem to be good choices for faster simulations. However, we still need to look at other results in the `_perflog.csv` file first before coming to that conclusion.

These example simulations each takes about three minutes or less to try. If your building takes much longer than a few minutes, you might want to temporarily change the run period to just a month or even a week to tune the PerformancePrecisionTradeoffs object inputs. If temporarily shortening the run period is necessary, it is best to pick a month or week that has some cooling and some heating. Just remember to set your run period back to a full year before coming to any conclusions about the building or energy efficiency options being considered for the building.

Table 1.4: PerfLog Energy Columns

Run	Direct Coil	Radiant Algorithm	Override Mode	Electricity [MJ]	Natural Gas [MJ]	Water [m <sup>3</sup> ]	Runtime [second]
1	FALSE	ScriptF	NORMAL	3,351,884	1,524,574	248,815	275.56
2	FALSE	ScriptF	MODE01	3,340,493	1,508,410	247,179	104.37
3	FALSE	ScriptF	MODE02	3,342,128	1,511,817	247,759	98.81
4	FALSE	ScriptF	MODE03	3,342,128	1,511,817	247,759	98.63
5	FALSE	ScriptF	MODE04	3,342,128	1,511,817	247,759	97.87
6	FALSE	ScriptF	MODE05	3,341,145	1,532,697	246,121	47.22
7	FALSE	ScriptF	MODE06	3,341,183	1,532,626	246,122	45.48
8	FALSE	ScriptF	MODE07	3,341,183	1,532,626	246,122	45.14
9	FALSE	ScriptF	MODE08	3,342,365	1,516,963	246,906	44.18
10	TRUE	ScriptF	NORMAL	3,351,884	1,524,574	248,816	273.42
11	FALSE	CarrollMRT	NORMAL	3,525,611	1,271,563	304,914	276.68
12	FALSE	CarrollMRT	MODE01	3,511,800	1,260,228	303,189	102.73
13	FALSE	CarrollMRT	MODE02	3,510,893	1,263,149	303,383	97.28
14	FALSE	CarrollMRT	MODE03	3,510,893	1,263,149	303,383	96.77
15	FALSE	CarrollMRT	MODE04	3,510,893	1,263,149	303,383	96.56
16	FALSE	CarrollMRT	MODE05	3,513,714	1,277,252	302,242	47.31
17	FALSE	CarrollMRT	MODE06	3,513,750	1,277,187	302,246	45.62
18	FALSE	CarrollMRT	MODE07	3,513,750	1,277,187	302,246	45.23
19	FALSE	CarrollMRT	MODE08	3,513,797	1,264,779	303,035	44.09

The CarrollMRT options seem to have a much more significant impact on the natural gas usage; and the total water and the times are similar to the runtimes using ScriptF. So for this example, CarrollMRT does not seem to be a right choice. In these cases, the computation times are not very different from the ScriptF instances; however, the energy usage is further away from the Normal baseline. The electricity usage differences for Runs 2 through 8 are small compared to Run 1 (the Normal baseline case), and are less than 0.34% different. The natural gas usage has more significant differences of 0.5% to 1.1%, and the water usage differs from 0.4% to 1.1%. From an energy perspective, these impacts for the ScriptF Runs 2 through 8 are probably tolerable.

Table 1.5: PerfLog Oscillation Columns

Run	Direct Coil	Radiant Algorithm	Override Mode	Oscillating [hour]	Oscillating Occupancy [hour]	Oscillating Deadband [hour]	Warnings	Runtime [second]
1	FALSE	ScriptF	NORMAL	2.6	2.25	0.18	64	275.56
2	FALSE	ScriptF	MODE01	7.87	2.67	6.87	65	104.37
3	FALSE	ScriptF	MODE02	8.7	3.5	7.7	66	98.81
4	FALSE	ScriptF	MODE03	8.7	3.5	7.7	67	98.63
5	FALSE	ScriptF	MODE04	8.7	3.5	7.7	68	97.87

6	FALSE	ScriptF	MODE05	169	94	119	70	47.22
7	FALSE	ScriptF	MODE06	169	94	119	71	45.48
8	FALSE	ScriptF	MODE07	169	94	119	72	45.14
9	FALSE	ScriptF	MODE08	161	94	115	2379	44.18
10	TRUE	ScriptF	NORMAL	2.6	2.25	0.18	65	273.42
11	FALSE	CarrollMRT	NORMAL	2.18	1.83	0.18	65	276.68
12	FALSE	CarrollMRT	MODE01	8.57	1.7	7.57	66	102.73
13	FALSE	CarrollMRT	MODE02	8.83	2.5	7.7	67	97.28
14	FALSE	CarrollMRT	MODE03	8.83	2.5	7.7	68	96.77
15	FALSE	CarrollMRT	MODE04	8.83	2.5	7.7	69	96.56
16	FALSE	CarrollMRT	MODE05	177	105	112	70	47.31
17	FALSE	CarrollMRT	MODE06	177	105	112	71	45.62
18	FALSE	CarrollMRT	MODE07	177	105	112	72	45.23
19	FALSE	CarrollMRT	MODE08	173	100	112	73	44.09

The number of hours any zone is oscillating for Run 1 (the Normal baseline case) using Script F is only 2.6 hours, with almost none of the hours in the dead band and nearly all during occupancy. This changes when considering the other ScriptF cases using Mode01 to Mode08 (Run 2 to Run 9). For Mode01 (Run 2), the oscillating hours increase but are still less than 8 hours per year. While more than doubling, it is still considered a small change on an absolute basis. The change is even more minor when considering the oscillating hours during occupancy. The oscillation hours in the dead band for Mode01 (Run 2) increase about 6 hours. For Mode02 to Mode04, there is an increase of about 1 hours for each oscillating hour categories (the total, the occupancy, and the dead band ones), though they are considered to be a relatively minor change from the Normal baselines especially when comparing further with those for the succeeding Mode05 and Mode08. For Mode05 to Mode08 (Runs 6 to 9), the oscillating hours increase significantly, by more than one order of magnitude to about 161–169 hours per year. The numbers are also reflected in similar fashions for the the oscillating hours during occupancy and for the oscillating hours during dead band. For the CarrollMRT cases, similar trends can be observed when applying Mode01 to Mode08. The most significant change starts from Mode05, which for both ScriptF and CarrollMRT raise the oscillating hours to about 173–177. This is a substantial change that does indicate a significant shift in the way the simulation program is behaving. On the other hand, the number of warnings for all the 19 cases are not too much different from each other ranging from 64 to 73, except for Run 9 which has 2,379 warnings. No severe errors are reported for any of these simulations, so no column is shown for them.

The decision on which mode to use is up to the individual modelers. These simulations runs can be clearly classified into three tiers based on the simulation speed (computation time) and the numerical stability (oscillation hours): the first tier is the normal run, which incurs the least oscillations (the best), but also takes the longest computation time; the second tier includes Mode02 to Mode04, where the simulation time can be cut to roughly one-third of that for the Normal baseline, but with a minor penalty for increased oscillation hours; and the third tier includes Mode05 to Mode08, which can achieve an superior simulation time advantage, reaching around one-fifth to one-seventh of that for the Normal baseline, but also with significant oscillation hours penalties of about one order of magnitude higher. For simulations conducted in these test modes, Runs 5 (Mode04) is recommended as a balanced option for speed and numerical stability (oscillations). It does not use direct coil solution, uses ScriptF, and Mode04. This simulation time also shows an advantages over the other lower modes cases—it saves time compared to Mode01–Mode03—and still has tamed the oscillating hours. Further, it does not add too much additional overrides compared to the higher modes (Mode05–Mode08), which should be avoided if not adding value. For

extreme speed benefit, higher modes such as Mode05 to Mode08 definitely show an advantage in the computation time, as they cost only about one-seventh to one-fifth of the normal base, and only about half of those for the lower modes (such as Mode02–Mode04). However, substantially higher oscillating hours will be incurred as a downside with these higher modes.

Additional guidance on how to make EnergyPlus faster appears in the “Tips And Tricks for Using EnergyPlus” document that is distributed with EnergyPlus within the section titled “Platforms and Run-Time.”

#### 1.5.17.0.2 Field: Use Coil Direct Solutions

If Yes, an analytical or empirical solution will be used instead of iteration based method in calculations that determine how to control the coil model. The tradeoff is between an iterative solution algorithm, see [HVACSystemRootFindingAlgorithm](#), or a direct solution algorithm as described below. These calculations are at the level of how the coil component model is to be controlled by the parent system object as it tries to find a part load ratio that just meets a coil load or coil leaving temperature condition. Once the control calculations have been completed to determine the part load ratio (or speed ratio for variable speed) the full coil model is still used for the final calculation.

Although this input field may eventually affect all coils, the current implementation is available for only the limited number of systems and coil configurations listed in the following table. Since a linear relationship between system output and part load ratio, or speed ratio, is expected, an analytical direct solution is applied to all coils in the listed in the table when Yes is selected. More coils will be allowed when time allows. Note that this simulation parameter is global and when used every such coil model included in the entire building model will be changed to use the direct method.

The Part Load Ratio (PLR) for a single speed coil or a multiple speed coil at speed 1 is calculated using the equation below:

$$\text{PLR} = \frac{\text{SystemLoad} - \text{OutputOff}}{\text{OutputFull} - \text{OutputOff}} \quad (1.2)$$

where

$\text{PLR}$  = Part load ratio for a single speed coil or for a multiple speed coil at speed 1;

$\text{SystemLoad}$  = Load requested to meet thermostat setpoint;

$\text{OutputOff}$  = System output at  $\text{PLR} = 0$  as coil off;

$\text{OutputFull}$  = System output at  $\text{PLR} = 1$  as full output.

The Speed Ratio for a multiple speed coil at speed  $> 1$  is calculated using the equation below:

$$\text{SpeedRatio} = \frac{\text{SystemLoad} - \text{OutputFull}_{i-1}}{\text{OutputFull}_i - \text{OutputFull}_{i-1}} \quad (1.3)$$

where

$\text{SpeedRatio}$  = Ratio to represent how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep;

$\text{SystemLoad}$  = Load requested to meet thermostat setpoint;

$\text{OutputFull}_i$  = System full output at the higher speed;

$\text{OutputFull}_{i-1}$  = System full output at the lower speed.

Note: When a DX cooling coil with a constant volume fan is used, latent degradation is disabled.

When coils of Coil:Cooling:DX:VariableSpeed, Coil:Heating:DX:SingleSpeed, and Coil:Heating:DX:VariableSpeed are applied, the desired outlet temperature is used to determine part load ratio or speed ratio.

The Part Load Ratio (PLR) for a single speed coil or a multiple speed coil at speed 1 is calculated using the equation below:

$$\text{PLR} = \frac{\text{DesOutTemp} - \text{InletTemp}}{\text{OutTempFull} - \text{InletTemp}} \quad (1.4)$$

where

$\text{PLR}$  = Part load ratio for a single speed coil or for a multiple speed coil at speed 1;

$\text{DesOutTemp}$  = Desired outlet temperature to meet setpoint;

$\text{InletTemp}$  = Inlet temperature;

$\text{OutTempFull}$  = Outlet temperature at  $\text{PLR} = 1$  as full output.

The Speed Ratio for a multiple speed coil at speed  $> 1$  is calculated using the equation below:

$$\text{SpeedRatio} = \frac{\text{DesOutTemp} - \text{OutTempFull}_{i-1}}{\text{OutTempFull}_i - \text{OutTempFull}_{i-1}} \quad (1.5)$$

where

$\text{SpeedRatio}$  = Ratio to represent how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep;

$\text{DesOutTemp}$  = Desired outlet temperature to meet setpoint;

$\text{OutTempFull}_i$  = Outlet temperature of full output at the higher speed;

$\text{OutTempFull}_{i-1}$  = Outlet temperature of full output at the lower speed.

Table 1.6: A list of air systems and associated coils allowed for direct solutions

System	Allowed Coil
AirLoopHVAC:UnitarySystem	Coil:Cooling:DX:SingleSpeed, Coil:Heating:DX:SingleSpeed, Coil:Heating:Electric, Coil:Heating:Fuel, Coil:Heating:DX:MultiSpeed, Coil:Cooling:DX
AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed	Coil:Heating:DX:MultiSpeed, Coil:Heating:Electric:MultiStage, Coil:Heating:Gas:MultiStage, Coil:Cooling:DX:MultiSpeed
CoilSystem:Cooling:DX	Coil:Cooling:DX:SingleSpeed, Coil:Cooling:DX:VariableSpeed
CoilSystem:Heating:DX	Coil:Heating:DX:SingleSpeed, Coil:Heating:DX:VariableSpeed

Note: The choice of Load in the Control Type of the AirLoopHVAC:UnitarySystem object is required for all coils listed in the above table. In addition, when Coil:Cooling:DX is specified under AirLoopHVAC:UnitarySystem, the following coil configurations are supported for Direct Solution:

Single speed mode at Nominal Speed Number = 1 in the Coil:Cooling:DX:CurveFit:OperatingMode

Multi speed mode at Nominal Speed Number > 1 in the Coil:Cooling:DX:CurveFit:OperatingMode

Single speed SubcoolReheat mode. The SubcoolReheat mode requires all inputs of 3 fields in the Coil:Cooling:DX:CurveFit:Performance: Base Operating Mode, Alternative Operating Mode 1, and Alternative Operating Mode 2.

#### 1.5.17.0.3 Field: Zone Radiant Exchange Algorithm

Allowed choices are: ScriptF (default) and CarrollMRT. ScriptF uses view factors among all surfaces in a zone and calculates radiant heat transfer from each surface in the zone to each other surface in the zone based on their respective temperatures and emissivities. The CarrollMRT algorithm calculates radiant heat transfer between surfaces which exchange heat through a central, mean radiant temperature (MRT) node.

Although, defined view factors cannot be used with CarrollMRT, the algorithm approximates “view factors” based on relative areas of the surfaces in a similar way to how EnergyPlus determines its default view factors. One exception is that with CarrollMRT, every surface can “view” every other surface in the zone regardless of orientation. For enclosed prism shapes, this approximation is very accurate.

#### 1.5.17.0.4 Field: Override Mode

The Override Mode field provides a single field that will override other inputs located in the IDF/epJSON file as well as convergence related values that appear in the remaining fields of the PerformancePrecisionTradeoffs object. The Normal option (default) provides no overrides while the Mode options provide overrides based on the following tables. The Advanced option, allows the MaxZoneTempDiff and MaxAllowedDelTemp fields of the PerformancePrecisionTradeoffs to be used.

Table 1.7: Override Modes

Mode	Description
Normal	No overrides
Mode01	Zone time step (TimeStep object) and the number of timesteps in averaging windows will be set to one timestep per hour. The averaging windows are used in data smoothing during sizing periods.
Mode02	Mode01 plus ZoneAirHeatBalanceAlgorithm will be set to Euler
Mode03	Mode02 plus Minimum Number of Warmup Days will be set to 1
Mode04	Mode03 plus Begin Environment Reset Mode will be set to SuppressAllBeginEnvironmentResets
Mode05	Mode04 plus minimum system timestep length will be 1 hour
Mode06	Mode05 plus use cubic spline interpolations in replacement of the psychrometric function PsyTsatFnPb
Mode07	Mode06 plus MaxZoneTempDiff will be set to 1.00
Mode08	Mode07 plus MaxAllowedDelTemp will be set to 0.1
Advanced	Allow direct input of convergence field values

The increasing mode number roughly corresponds with increased speed. Mode01 to Mode05 are overriding inputs in other parts of the IDF/epJSON file and is equivalent to changing those input directly. Mode06 offers an alternative method to calculate saturated temperature given pressure in replacement of the psychrometric function PsyTsatFnPb. Mode07 and Mode08 are changing convergence parameters previously not available to be modified by the user.

#### **1.5.17.0.5 Field: MaxZoneTempDiff**

This field is only active and used when Override Mode is set to Advanced. The value provided here is used for the MaxZoneTempDiff variable within EnergyPlus. This variable sets the maximum zone temperature change before the HVAC timestep is shortened. Larger values result in fewer iterations. To understand this input completely, please review the use of the MaxZoneTempDiff variable in the ManageHVAC() routine located in the HVACManager.cc source file of EnergyPlus. The value normally used in EnergyPlus is 0.3 ( $^{\circ}\text{C}$ ), which is also the default value. Testing has been done with a value of 1.0 ( $^{\circ}\text{C}$ ), which increased the overall speed of EnergyPlus for most of a set of selected files that were tested. Values larger than 1.0 have not been tested.

#### **1.5.17.0.6 Field: MaxAllowedDelTemp**

This field is only active and used when Override Mode is set to Advanced. The value provided here is used for the MaxAllowedDelTemp variable within EnergyPlus. This variable sets the maximum surface temperature change before the HVAC timestep is shortened. Similar to the MaxZoneTempDiff parameter, larger MaxAllowedDelTemp values result in fewer iterations. To understand this input completely, please review the use of the MaxAllowedDelTemp variable in the CalcHeatBalanceInsideSurf2() routine located in the HeatBalanceSurfaceManager.cc source file of EnergyPlus. The value normally used in EnergyPlus is 0.002 ( $^{\circ}\text{C}$ ), which is also the default value. Testing has been done with a value of 0.1 ( $^{\circ}\text{C}$ ), which increased the overall speed of EnergyPlus for most of a set of selected files that were tested. Values larger than 0.1 have not been tested.

#### **1.5.17.0.7 Field: Use Representative Surfaces for Calculations**

If Yes, EnergyPlus will automatically group heat-transfer surfaces with similar characteristics and perform relevant calculations only once for each group.

Surface are grouped based on the following criteria for similarity:

- construction
- orientation
- surface height
- zone
- enclosure
- solar/wind exposure
- other side boundary condition
- conduction and convection heat transfer algorithms

- movable insulation
- frame and divider (windows only)
- storm window construction (windows only)
- other minor attributes

Surfaces with the following objects defined are currently never grouped because there is a high likelihood that they will experience dissimilar conditions throughout a simulation:

- ConstructionProperty:InternalHeatSource
- ZoneProperty:UserViewFactors:BySurfaceName
- WindowShadingControl
- WindowProperty:AirflowControl
- WindowMaterial:GlazingGroup:Thermochromic
- DaylightingDevice:Tubular
- WindowsCalculationEngine
- SurfaceProperty:SolarIncidentInside

Surface heat balance and interior radiation exchange calculations are performed across all surfaces within a group. Surface heat balance calculations are skipped for all but one surface within a group, and subsequently updated using the results from the representative surface. For interior radiation exchange, surfaces within a group are collected into a single area for participating in interior longwave radiation exchange. This will reduce the scale and complexity of the algorithm with minimal impact on accuracy. Solar shading and interior solar distribution are still calculated for each individual surface. The absorbed solar radiation used for the surface heat balance equations within a group is the area weighted average of all surfaces within the group.

An IDF example:

```
PerformancePrecisionTradeoffs,
Yes,                      !- Use Coil Direct Solutions
CarrollMRT;               !- Zone Radiant Exchange Algorithm
Mode06,                   !- Override Mode
0.3,                      !- MaxZoneTempDiff
0.002,                   !- MaxAllowedDelTemp
Yes;                      !- Use Representative Surfaces for Calculations
```

### 1.5.18 HVACSystemRootFindingAlgorithm

The HVACSystemRootFindingAlgorithm object provides a way to select what type of solution algorithm will be used to find a part load ratio or mass flow rate at given equipment/system load in HVAC system simulations. This object is an optional object. If the default algorithm is used, this object is not required in an input file.

### 1.5.18.1 Inputs

#### 1.5.18.1.1 Field: Algorithm

Five choices are allowed to select which solution algorithm will be used: RegulaFalsi, Bisection, BisectionThenRegulaFalsi, RegulaFalsiThenBisection, and Alternation. The RegulaFalsi selection is the default selection. Bisection selection will allow the program to use the bisection method to get a solution. The BisectionThenRegulaFalsi selection requires the program to apply the bisection method first. After the number of iteration is above the value defined in the next field, the RegulaFalsi algorithm will be applied. The RegulaFalsiThenBisection selection requires the program to apply the RegulaFalsi method first. After the number of iteration is above the value defined in the next field, the bisection algorithm will be applied. The Alternation selection forces number of iteration (defined in the next field) using RegulaFalsi first. Then Bisection and RegulaFalsi algorithm will be alternated after the number of iteration is above the value defined in the next field.

#### 1.5.18.1.2 Field: Number of Iterations Before Algorithm Switch

This field is used when RegulaFalsiThenBisection or BisectionThenRegulaFalsi or Alternation is entered. When the iteration number is greater than the value, algorithm switches either from RegulaFalsi to Bisection or from Bisection to RegulaFalsi with choices of RegulaFalsiThenBisection or BisectionThenRegulaFalsi.

An IDF example:

```
HVACSystemRootFindingAlgorithm,
  RegulaFalsiThenBisection, !- Algorithm
  20;                                !- Number of Iteration Before Algorithm Switch
```

---

### 1.5.19 Meter:Custom

A custom meter allows the user to group variables or meters onto a virtual meter that can be used just like a normal meter created by EnergyPlus. For consistency, the items being grouped must all be similar. A Meter:Custom cannot reference another Meter:Custom.

#### 1.5.19.1 Inputs

##### 1.5.19.1.1 Field: Name

This is a user defined name for the custom meter. Names for custom meters cannot duplicate internal meter names.

##### 1.5.19.1.2 Field: Resource Type

A resource type should be specified for the meter. All assignments to this meter will be checked to assure that the same resource type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- Propane

- FuelOilNo1
- FuelOilNo2
- Diesel
- Gasoline
- Coal
- OtherFuel1
- OtherFuel2
- Steam
- DistrictHeating
- DistrictCooling
- Water
- Generic

Resource types are generally self-explanatory. Generic is included for convenience when a custom meter is defined that doesn't quite fit the "resource" categories. See the examples below.

#### 1.5.19.1.3 Field: group(s) Key Name-Output Variable/Meter Name

The rest of the object is filled with parameters of the key name/output variable or meter names. When a meter name is used, the key name field is left blank.

#### 1.5.19.1.4 Field: Key Name #

A key name field is used when the following field specifies an output variable. If the field is left blank, then all the output variables in the following field are assigned to the meter.

#### 1.5.19.1.5 Field: Output Variable or Meter Name #

This field must be a valid output variable name or a valid meter name. If a Meter:Custom references another Meter:Custom it will generate a warning and not produce any output. For output variables, only summed variables are valid. For example from the rdd output, any Sum type variable is valid:

```
Zone,Sum,Exterior Equipment Electricity Energy [J]
```

## 1.5.20 Meter:CustomDecrement

The decrement custom meter is very similar to the custom meter specification but additionally allows a predefined meter to be used as the "source" meter and the remaining items subtract from that predefined meter.

### 1.5.20.1 Inputs

#### 1.5.20.1.1 Field: Name

This is a user defined name for the custom meter. Names for custom meters cannot duplicate internal meter names.

#### 1.5.20.1.2 Field: Resource Type

A resource type should be specified for the meter. All assignments to this meter will be checked to assure that the same resource type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- Propane
- FuelOilNo1
- FuelOilNo2
- Diesel
- Gasoline
- Coal
- OtherFuel1
- OtherFuel2
- Steam
- DistrictHeating
- DistrictCooling
- Water
- Generic

#### 1.5.20.1.3 Field: Source Meter Name

This name specifies the meter that will be used as the main source for the decrement custom meter. The remainder of the fields are subtracted from the value of this meter to create the meter value named above. The Source Meter is not changed in any way by including this custom meter.

#### 1.5.20.1.4 Field: group(s) Key Name-Output Variable/Meter Name

The rest of the object is filled with parameters of the key name/output variable or meter names. When a meter name is used, the key name field is left blank.

### 1.5.20.1.5 Field: Key Name #

A key name field is used when the following field specifies an output variable. If the field is left blank, then all the output variables in the following field are assigned to the meter.

### 1.5.20.1.6 Field: Output Variable or Meter Name #

This field must be a valid output variable name or a valid meter name. Additionally, it must be contained on the Source Meter. Note that, if an error occurs, only the Variable in error will show – confusing things if what was entered was a meter name. For output variables, only summed variables are valid. For example from the rdd output, any Sum type variable is valid:

```
Zone,Sum,Exterior Equipment Electricity Energy [J]
```

## 1.5.21 Custom Meter Examples

Details of the [Meter:Custom/Meter:CustomDecrement](#) are shown on the Meter Details file.

In the following examples, the custom meters are set up to illustrate the capabilities of custom meters. Custom meter “**MyGeneralLights**” duplicates the InteriorLights:Electricity meter. Custom meter “**MyBuildingElectric**” duplicates the Electricity:Building meter (by specifying that meter). Custom Meter (Decrement) “**MyBuildingOther**” uses the Electricity:Building meter as the source meter and subtracts out the values for MyGeneralLights (aka InteriorLights:Electricity). The resultant value for the MyBuildingOther meter should be equal to the value for the meters Electricity:Building – InteriorLights:Electricity.

```
Meter:Custom,
MyGeneralLights,      !- Name
Electricity,          !- Resource Type
SPACE1-1,             !- Key Name 1
Lights Electricity Energy, !- Output Variable or Meter Name 1
SPACE2-1,             !- Key Name 2
Lights Electricity Energy, !- Output Variable or Meter Name 2
SPACE3-1,             !- Key Name 3
Lights Electricity Energy, !- Output Variable or Meter Name 3
SPACE4-1,             !- Key Name 4
Lights Electricity Energy, !- Output Variable or Meter Name 4
SPACE5-1,             !- Key Name 5
Lights Electricity Energy; !- Output Variable or Meter Name 5

Meter:Custom,
MyBuildingElectric,   !- Name
Electricity,          !- Resource Type
,                   !- Key Name #1
Electricity:Building; !- Output Variable or Meter Name #1

Meter:CustomDecrement,
MyBuildingOther,       !- Name
Electricity,          !- Resource Type
Electricity:Building, !- Source Meter Name
,                   !- Key Name #1
MyGeneralLights;      !- Output Variable or Meter Name #1
```

For an example of “generic” Resource type, one might put the Building Infiltration Heat Loss & Heat Gain on a set of custom meters:

```
Meter:Custom,
Building Infiltration Heat Loss,      !- Name
Generic,                          !- Resource Type
*,                                !- Key Name 1
Zone Infiltration Total Heat Loss Energy; !- Output Variable Name 1
```

---

```
Meter:Custom,
Building Infiltration Heat Gain,           !- Name
Generic,                                     !- Resource Type
*,                                           !- Key Name 1
Zone Infiltration Total Heat Gain Energy; !- Output Variable Name 1
```

---

One can then report these values the same way one reports other standard meters.

## 1.5.22 Simulation Parameter Outputs

These appear in the **eplusout.eio** file. For details of the reporting, please see the Output Details and Examples document.

# 1.6 Group – Compliance Objects

Not necessarily related directly to simulation, the Compliance Object group provides a repository for a group of objects that can be used directly or indirectly in reporting compliance (such as ASHRAE 90.1) to building standards.

## 1.6.1 Compliance:Building

The Compliance:Building object describes parameters related to compliance to building standards, building codes, and beyond energy code programs.

### 1.6.1.1 Inputs

#### 1.6.1.1.1 Field: Building Rotation for Appendix G

Building Rotation for Appendix G allows for the building model to be rotated for use with compliance such as ASHRAE 90.1 Appendix G. Appendix G requires the building to be rotated 0, 90, 180 and 270 degrees and the values averaged to establish baseline energy use. This input works with relative or world coordinate systems.

An example from an IDF:

---

```
Compliance:Building,
90;          !- Building Rotation for Appendix G
```

---

# 1.7 Group – Location – Climate – Weather File Access

This group of objects describes the ambient conditions for the simulation.

## 1.7.1 Site:Location

The location class describes the parameters for the building's location. Only one location is allowed. Weather data file location, if it exists, will override any location data in the IDF. Thus, for an annual simulation, a Location does not need to be entered.

### 1.7.1.1 Inputs

#### 1.7.1.1.1 Field: Name

This alpha field is used as an identifying field in output reports.

#### 1.7.1.1.2 Field: Latitude

This field represents the latitude (in degrees) of the facility. By convention, North Latitude is represented as positive; South Latitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.7.1.1.3 Field: Longitude

This field represents the longitude (in degrees) of the facility. By convention, East Longitude is represented as positive; West Longitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.7.1.1.4 Field: Time Zone

This field represents the time zone of the facility (relative to Greenwich Mean Time or the 0<sup>th</sup> meridian). Time zones west of GMT (e.g. North America) are represented as negative; east of GMT as positive. Non-whole hours can be represented in decimal (e.g. 6:30 is 6.5).

#### 1.7.1.1.5 Field: Elevation

This field represents the elevation of the facility in meters (relative to sea level).

Units with their abbreviations are shown in Appendix A. And, as shown in an IDF:

```
Site:Location, DENVER COLORADO, ! Name
  39.75000,           ! Latitude {N+ S-}
  -104.8700,          ! Longitude {W- E+}
  -7.000000,          ! TimeZoneNumber {GMT+/-}
  1610.26;            ! Elevation {m}
```

Most examples in this document include the comment lines that illustrate each data field's value. However, this is not necessary (though it makes the IDF more readable). The previous example could also be:

```
Site:Location, DENVER COLORADO,39.75,-104.87,-7,1610.26;
```

## 1.7.2 Site:VariableLocation

This variable location class describes the parameters for a moving and/or rotating building's location. The applications for this include:

- a vehicle driving along the road,
- a rotating building, such as for experimental testing at different orientations, or
- if combined with a “SurfaceProperty:Underwater” boundary condition, it could apply to ships and vessels.

The latitude, longitude, and orientation are all defined according to the same conventions as in the regular “Site:Location” object.

### 1.7.2.1 Inputs

#### 1.7.2.1.1 Field: Name

This alpha field is used as an identifying field in output reports.

#### 1.7.2.1.2 Field: Building Location Latitude Schedule

This field represents the latitude (in degrees) of the facility. By convention, North Latitude is represented as positive; South Latitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.7.2.1.3 Field: Building Location Longitude Schedule

This field represents the longitude (in degrees) of the facility. By convention, East Longitude is represented as positive; West Longitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.7.2.1.4 Field: Building Location Orientation Schedule

This field represents the time zone of the facility (relative to Greenwich Mean Time or the 0<sup>th</sup> meridian). Time zones west of GMT (e.g. North America) are represented as negative; east of GMT as positive. Non-whole hours can be represented in decimal (e.g. 6:30 is 6.5).

As shown in an IDF:

```

Site:VariableLocation,
  MovingAndRotatingBuilding, !- Name
  LatitudeSchedule,          !- Building Location Latitude Schedule
  LongitudeSchedule,         !- Building Location Longitude Schedule
  OrientationSchedule;       !- Building Location Orientation Schedule

Schedule:File,
  LatitudeSchedule,          !- Name
  ,                         !- Schedule Type Limits Name
  TripLog.csv,               !- File Name
  2,                         !- Column Number

```

### 1.7.3 SizingPeriod:DesignDay

The design day input describes the parameters to effect a “design day” simulation, often used for load calculations or sizing equipment. Using the values in these fields, EnergyPlus “creates” a complete days’ worth of weather data (air temperatures, solar radiation, etc.) Normal operation uses the default range multipliers as shown in Figure 1.6 though users may choose to input their own multiplier schedule. Likewise, normal operation specifies one “humidity indicating condition”

which is used to calculate the humidity ratio at maximum temperature – this is used as the constant humidity ratio for the entire day. Again, this can be overridden by specifying a relative humidity schedule or requesting generation of an hourly wet-bulb temperature profile. Multiple design days may be specified.

We refer you to the ASHRAE Handbook of Fundamentals for philosophy of what parameters are important for use as “design conditions” in sizing equipment.

In the install, the “design day files” are included for the weather file locations that are included (weatherdata folder). All the design day definitions from the ASHRAE design conditions (latest publication date) are included, grouped by WMO region, on the main web site with the weather data. <https://www.energyplus.net/weather> These files are in “macro” form but it is easy to cut and paste the appropriate definition segments. These files include the location information as well as some locations have **RunPeriodControl:DaylightSavingTime** objects.

### 1.7.3.1 Inputs

#### 1.7.3.1.1 Field: Name

This field, like the location name, is used simply for reporting and identification. This name must be unique among the SizingPeriod names entered.

#### 1.7.3.1.2 Field: Month

This numeric field specifies the month. That, in conjunction with the day of the month and location information, determines the current solar position and solar radiation values for each hour of the day.

#### 1.7.3.1.3 Field: Day of Month

This numeric field specifies the day of the month. That, in conjunction with the month and location information, determines the current solar position and solar radiation values for each hour of the day.

#### 1.7.3.1.4 Field: Day Type

This alpha field specifies the day type for the design day. This value indicates which day profile to use in schedules. For further information, see the Schedule discussion later in this document. (ref: Schedule) Note that two of the possible day types are SummerDesignDay (for cooling) and WinterDesignDay (for heating) – allowing the user to customize schedules for the design conditions. That is, for design days tagged with a SummerDesignDay type, you can set schedules to be worst or typical schedules for a cooling season.

#### 1.7.3.1.5 Field: Maximum Dry-Bulb Temperature

This numeric field should contain the day’s maximum dry-bulb temperature in degrees Celsius. (Reference Appendix A of this document for EnergyPlus standard units and abbreviations). The MacroDataSets design day files show extreme temperature for locations as indicated in the ASHRAE HOF design condition tables.

### 1.7.3.1.6 Field: Daily Dry-bulb Temperature Range

A design day can have a “high” temperature and a “low” temperature (or can be a constant temperature for each hour of the day). If there is a difference between high and low temperatures, this field should contain the difference from the high to the low. EnergyPlus, by default, distributes this range over the 24 hours in the day as shown in the figure below:

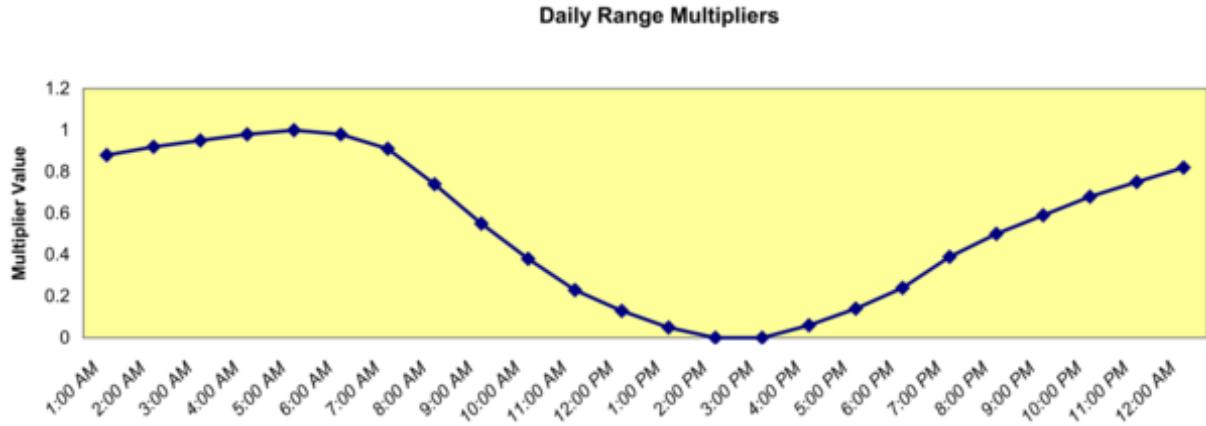

Figure 1.6: Default Daily range Multiplier for Design Days

The multipliers are taken from the ASHRAE 2009 HOF. More explicitly, EnergyPlus creates an air temperature for each timestep by using the entered maximum dry-bulb temperature in conjunction with the entered daily range and the above multiplier values. The actual equation used is shown below:

$$T_{current} = T_{Max} - T_{range} \cdot T_{Multiplier} \quad (1.6)$$

where

$T_{current}$  = Air temperature of current Hour of Day

$T_{Max}$  = User supplied Max Dry-bulb Temperature

$T_{range}$  = User supplied Daily Temperature Range

$T_{Multiplier}$  = Range multiplier as shown on the above graph

The range multiplier values represent typical conditions of diurnal temperatures (i.e. the low temperature for the day occurring about 5:00 AM and the maximum temperature for the day occurring about 3:00 PM. Note that EnergyPlus does not shift the profile based on the time of solar noon as is optionally allowed in ASHRAE procedures.

ASHRAE research indicates that dry-bulb and wet-bulb temperatures typically follow the same profile, so EnergyPlus can use the default profile to generate humidity conditions (see Humidity Indicating Type = WetBulbProfileDefaultMultipliers below).

### 1.7.3.1.7 Field: Dry-Bulb Temperature Range Modifier Type

If you are happy with lows at 5am and highs at 3pm, you can ignore this field. If you want to specify your own temperature range multipliers (see earlier discussion at the Temperature Range field description), you can specify a type here and create a day schedule which you reference in the next field.

If you specify **MultiplierSchedule** in this field, then you need to create a day schedule that specifies a multiplier applied to the temperature range field (above) to create the proper dry-bulb temperature range profile for your design day.

If you specify **DifferenceSchedule** in this field, then you need to create a day schedule that specifies a number to be **subtracted** from dry-bulb maximum temperature for each timestep in the day. Note that numbers in the delta schedules cannot be negative as that would result in a higher maximum than the maximum previously specified.

If you specify **TemperatureProfileSchedule** in this field, then you need to create a day schedule that specifies the actual dry-bulb temperatures throughout the day. You will not need to include a Maximum Dry-Bulb Temperature in that field.

If you leave this field blank or enter **DefaultMultipliers**, then the default multipliers will be used as shown in the “temperature range” field above.

#### 1.7.3.1.8 Field: Dry-Bulb Temperature Range Modifier Day Schedule Name

This field is the name of a **day schedule** (ref. [Schedule:Day:Hourly](#), [Schedule:Day:Interval](#), [Schedule:Day>List](#) objects) with the values as specified in the Dry-Bulb Temperature Range Modifier Type field above.

#### 1.7.3.1.9 Field: Humidity Condition Type

The values/schedules indicated here and in subsequent fields create the humidity values in the 24 hour design day conditions profile. Valid choices here are: **WetBulb**, **Dewpoint**, **WetBulbProfileDefaultMultipliers**, **WetBulbProfileDifferenceSchedule**, **WetBulbProfileMultipliers**, **HumidityRatio**, **Enthalpy**, and **Schedule**.

The Humidity Condition Type fields have interacting uses and units, summarized as follows:

Table 1.8: Humidity Indicating Field Interactions -  
Design Day

Humidity Condition Type	Primary Indicating Field	Humidity Indicating Field	Humidity Schedule	Indicating Day
WetBulb	Wetbulb or DewPoint at Maximum Dry-Bulb		N/A (unused)	
DewPoint	Wetbulb or DewPoint at Maximum Dry-Bulb		N/A (unused)	
HumidityRatio	Humidity Ratio at Maximum Dry-Bulb		N/A (unused)	
Enthalpy	Enthalpy at Maximum Dry-Bulb		N/A (unused)	
WetBulbProfile- DefaultMultipliers	Wetbulb or DewPoint at Maximum Dry-Bulb		N/A (unused)	
WetBulbProfile- MultiplierSchedule	Wetbulb or DewPoint at Maximum Dry-Bulb	Fractions of wet-bulb daily range (0 – 1)		

Table 1.8: Humidity Indicating Field Interactions - Design Day

Humidity Condition Type	Primary Humidity Indicating Field	Humidity Indicating Day Schedule	
WetBulbProfile-DifferenceSchedule	Wetbulb or DewPoint at Maximum Dry-Bulb	Difference maximum hour/timestep temperature, C	between and wet-bulb
RelativeHumiditySchedule	N/A	Relative humidity (%), 0 – 100)	

Humidity conditions over the day are derived as follows:

#### **WetBulb, DewPoint, HumidityRatio, or Enthalpy:**

These four methods assume constant absolute humidity over the day. Calculate W = humidity ratio at Maximum Dry-Bulb Temperature and Humidity Indicating Conditions. Derive hourly/timestep humidity conditions from W and hour/timestep dry-bulb temperature.

#### **WetBulbProfileDefaultMultipliers**

Generate the wet-bulb temperature profile using Default Daily Range Multiplier for Design Days (shown in Figure 1.6 above) and Daily Wet-Bulb Temperature Range (below). This method is analogous to DefaultMultiplier generation of the dry-bulb temperature profile and is the procedure recommended in Chapter 14 of ASHRAE 2009 HOF.

#### **WetBulbProfileMultiplierSchedule**

Generate the wet-bulb profile using multipliers from the Humidity Indicating Day Schedule and Daily Wet-Bulb Temperature Range (below). Analogous to dry-bulb MultiplierSchedule.

#### **WetBulbProfileDifferenceSchedule**

Generate the wet-bulb profile by subtracting Humidity Indicating Day Schedule values from the daily maximum wet-bulb temperature (specified in Humidity Indicating Conditions at Maximum Dry-Bulb). Analogous to dry-bulb DifferenceSchedule.

#### **RelativeHumiditySchedule**

Hourly relative humidity is specified in Humidity Indicating Day Schedule.

In all cases, the humidity ratio is limited to saturation at the hour/timestep dry-bulb (that is, the dry-bulb temperature is used as specified, but the humidity ratio is modified as needed to be physically possible). Once a valid air state is determined, a complete set of consistent hour/timestep psychrometric values (dewpoint, wet-bulb, and enthalpy) is derived.

##### **1.7.3.1.10 Field: Wetbulb or DewPoint at Maximum Dry-Bulb**

If you choose **Wetbulb** or **Dewpoint** in the Humidity Condition Type field, then this numeric field should contain that value. Note that this field is unnecessary when you put in a humidity indicating day schedule (described later in this section).

##### **1.7.3.1.11 Field: Humidity Condition Day Schedule Name**

Allows specification a day schedule (ref. [Schedule:Day:Hourly](#), [Schedule:Day:Interval](#), [Schedule:Day>List](#) objects) of values for relative humidity or wet-bulb profile per Humidity

Indicating Type field.

#### 1.7.3.1.12 Field: Humidity Ratio at Maximum Dry-Bulb

If **HumidityRatio** is chosen for the Humidity Condition Type field, then this numeric field should contain the desired humidity ratio at maximum dry-bulb temperature (units kg Water / kg Dry Air).

#### 1.7.3.1.13 Field: Enthalpy at Maximum Dry-Bulb

If **Enthalpy** is chosen for the Humidity Condition Type field, then this numeric field should contain the desired enthalpy at maximum dry-bulb temperature (units Joules /kg).

#### 1.7.3.1.14 Field: Daily Wet-Bulb Temperature Range

The difference between the maximum and minimum wet-bulb temperatures on the design day (Celsius). Used for generating daily profiles of humidity conditions when Humidity Condition Type field (above) is **WetBulbProfileDefaultMultipliers** or **WetBulbProfileMultiplierSchedule**. Values for wet-bulb temperature range are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE 2009 HOF.

#### 1.7.3.1.15 Field: Barometric Pressure

This numeric field is the constant barometric pressure (Pascals) for the entire day.

#### 1.7.3.1.16 Field: Wind Speed

This numeric field is the wind speed in meters/second (constant throughout the day) for the day. The MacroDataSets design day files includes wind speed values (99.6% - heating, 1% cooling) as indicated in ASHRAE HOF design condition tables. But, you should be aware that traditional values for these are 6.7056 m/s (15 mph) for heating and 3.3528 m/s (7 mph) for cooling. A reminder is shown in the comments for the wind speed values. The comments also note the extreme wind speeds from the ASHRAE tables.

#### 1.7.3.1.17 Field: Wind Direction

This numeric field is the source wind direction in degrees. By convention, winds from the North would have a value of 0., from the East a value of 90.

#### 1.7.3.1.18 Field: Rain Indicator

This field indicates whether or not the building surfaces are wet. If the value is Yes, then it is assumed that the building surfaces are wet. Wet surfaces may change the conduction of heat through the surface.

#### 1.7.3.1.19 Field: Snow Indicator

This field indicates whether or not there is snow on the ground. If the value is Yes, then it is assumed there is snow on the ground. Snow on the ground changes the ground reflectance properties.

### 1.7.3.1.20 Field: Daylight Saving Time Indicator

This field specifies whether to consider this day to be a Daylight Saving Day. Yes in the field indicates that daylight saving time is operational for this day. Yes essentially adds 1 hour to the scheduling times used in items with schedules.

### 1.7.3.1.21 Field: Solar Model Indicator

This field allows the user to select **ASHRAEClearSky**, **ASHRAETau**, **ASHRAETau2017**, **ZhangHuang**, or **Schedule** for solar modeling in the calculation of the solar radiation in the design day. ASHRAEClearSky and ZhangHuang use the Clearness value as part of their calculations. ASHRAETau invokes the revised model specified in Chapter 14 of the ASHRAE 2009 HOF and uses Taub and Taud values (below) and ASHRAETau2017 invokes the revised model specified in Chapter 14 of the ASHRAE 2017 HOF and uses Taub and Taud values (below). Technical details of the models are described in the Engineering Reference. The **Schedule** choice allows you to enter schedule values for the day's profile (use the next two fields for the names).

### 1.7.3.1.22 Field: Beam Solar Day Schedule Name

This field allows the option for you to put in your own day profile of beam solar values (wh/m<sup>2</sup>). These values will replace the calculated values during design day processing. Only day schedules (ref. **Schedule:Day:Hourly**, **Schedule:Day:Interval**, **Schedule:Day>List** objects) are used here.

### 1.7.3.1.23 Field: Diffuse Solar Day Schedule Name

This field allows the option for you to put in your own day profile of diffuse solar values (wh/m<sup>2</sup>). These values will replace the calculated values during design day processing. Only day schedules (ref. **Schedule:Day:Hourly**, **Schedule:Day:Interval**, **Schedule:Day>List** objects) are used here.

### 1.7.3.1.24 Field: ASHRAE Clear Sky Optical Depth for Beam Irradiance (taub)

Optical depth for beam radiation, used only when Solar Model Indicator is ASHRAETau or ASHRAETau2017. See next field.

### 1.7.3.1.25 Field: ASHRAE Clear Sky Optical Depth for Diffuse Irradiance (taud)

Optical depth for diffuse radiation, used only when Solar Model Indicator is ASHRAETau or ASHRAETau2017. Taub and Taud values are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE HOF. ASHRAETau model Taub and Taud values are used from the 2009 ASHRAE HOF and ASHRAETau2017 model Taub and Taud values are used from either 2013 or 2017 ASHRAE HOF as needed.

### 1.7.3.1.26 Field: Sky Clearness

If the choice in the Solar Model Indicator field is ASHRAEClearSky or ZhangHuang, then this numeric field should be entered. This value represents the “clearness” value for the day. This value, along with the solar position as defined by the Location information and the date entered for the design day, help define the solar radiation values for each hour of the day. Clearness may range from 0.0 to 1.2, where 1.0 represents a clear sky at sea level. Values greater than 1.0 may be used for high altitude locations. Traditionally, one uses 0.0 clearness for Winter Design Days. Note that this “sky clearness” does not have the same meaning as output variable “Site Daylighting Model Sky Clearness”.

### 1.7.3.1.27 Field: Maximum Number Warmup Days

Optional integer number of days for an upper limit on the number of warmup days when running this sizing period. This overrides the global maximum set in the Building object for this particular design day.

### 1.7.3.1.28 Field: Begin Environment Reset Mode

Optional choice field to control if zone heat balance history terms should be reset when beginning to run this sizing period. This can reduce the number of warmup days needed to reach zone convergence. The options are **FullResetAtBeginEnvironment** or **SuppressThermalResetAtBeginEnvironment**. **FullResetAtBeginEnvironment** means that at the beginning of the design day warmup the building model's surfaces are set to 23 degrees C, which is the usual starting point for each environment. **SuppressThermalResetAtBeginEnvironment** means that at the beginning of the design day warmup the building model's surfaces are not reset and will just retain whatever thermal history results they had at the end of the previous design day. The warmup days still proceed as usual but because the initial condition is closer it needs fewer warmup days to reach convergence. This is available to reduce simulation run time when using many design days that are similar to each other.

Look at the example files 1ZoneUncontrolled\_DDChanges.idf and 1ZoneUncontrolled\_DD2009 for several examples of specifying Design Day inputs.

### 1.7.3.2 Outputs

For the schedule fields in the object, several output variables can be used:

- Zone,Average,Sizing Period Site Beam Solar Schedule Value [W/m<sup>2</sup>]
- Zone,Average,Sizing Period Site Diffuse Solar Schedule Value [W/m<sup>2</sup>]
- Zone,Average,Sizing Period Site Humidity Condition Schedule Value [%]
- Zone,Average,Sizing Period Site Humidity Condition Schedule Value []
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value []
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [deltaC]
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [C]
- Zone,Average,Sizing Period Site Sky Temperature Schedule Value [deltaC]
- Zone,Average,Sizing Period Site Sky Temperature Schedule Value [C]

#### 1.7.3.2.1 Sizing Period Site Beam Solar Schedule Value [W/m<sup>2</sup>]

#### 1.7.3.2.2 Sizing Period Site Diffuse Solar Schedule Value [W/m<sup>2</sup>]

This schedule value is active when any Design Day objects have / use the solar schedule option. For those objects that don't have this option, the value will be displayed as -999.

#### 1.7.3.2.3 Sizing Period Site Humidity Condition Schedule Value [%]

#### 1.7.3.2.4 Sizing Period Site Humidity Condition Schedule Value []

This schedule value is active when any Design Day objects have / use the humidity schedule option. For those objects that don't have this option, the value will be displayed as -999.

#### 1.7.3.2.5 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value []

#### 1.7.3.2.6 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [deltaC]

#### 1.7.3.2.7 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [C]

This schedule value is active when any Design Day objects have / use the drybulb temperature range modifier schedule option. For those objects that don't have this option, the value will be displayed as -999.

#### 1.7.3.2.8 Sizing Period Site Sky Temperature Schedule Value [deltaC]

#### 1.7.3.2.9 Sizing Period Site Sky Temperature Schedule Value [C]

This schedule value is active when any Design Day objects have / use the WeatherProperties:SkyTemperature schedule option. For those objects that don't have this option, the value will be displayed as -999.

### 1.7.4 Longer Design Periods

Some features may benefit by using a longer design weather period for sizing or loads calculations. Longer design periods may be created by using the **SizingPeriod:WeatherFileDays** or **SizingPeriod:WeatherFileConditionType** objects. These two objects allow for selections from an attached weather file to be used in the sizing calculations.

### 1.7.5 SizingPeriod:WeatherFileDays

The **SizingPeriod:WeatherFileDays** object describes using a selected period from the “attached” weather file to be used in load calculations or sizing equipment. The period selected can be as small as a single day or larger. Multiple periods may be input. While this object may be used for sizing calculations, you should also consider using design days that represent more long term extremes or conditions.

#### 1.7.5.1 Inputs

##### 1.7.5.1.1 Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

##### 1.7.5.1.2 Field: Begin Month

This numeric field should contain the starting month number (1 = January, 2 = February, etc.) for the annual run period desired.

```

WinterDesignDay,
No,                                     !- Day type
No;                                      !- Use Weather File Daylight Saving Period
                                         !- Use Weather File Rain and Snow Indicators

```

---

## 1.7.6 SizingPeriod:WeatherFileConditionType

When the EPW files are created, a heuristic procedure identifies extreme and typical periods in the actual weather file. This object will allow one of those periods to be selected for sizing or load calculations (typically). Multiple objects may be input. While this object may be used for sizing calculations, you should also consider using design days that represent more long term extremes or conditions.

### 1.7.6.1 Inputs

#### 1.7.6.1.1 Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

#### 1.7.6.1.2 Field: Period Selection

This field allows the generic period calculated from the weather file to be selected for this run period. It is not completely generic as there may be extreme cold periods in some weather files but extreme wet periods (tropical) in others. Not all weather files have all of the valid choices. The choices for this field are:

- SummerExtreme
- SummerTypical
- WinterExtreme
- WinterTypical
- AutumnTypical
- SpringTypical
- WetSeason
- DrySeason
- NoDrySeason
- NoWetSeason
- TropicalHot
- TropicalCold

### 1.7.6.1.3 Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) or special days (SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2) must be entered in this field. To clarify, this value will be used as the Start Day (type) for this sizing period. When weekdays are used, each subsequent day in the period will be incremented. When SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2 – are used, the day type will be applied for the entire period.

### 1.7.6.1.4 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving Period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving Period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

### 1.7.6.1.5 Field: Use Weather File Rain and Snow Indicators

Weather files can contain “rain” and “snow” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Snow indicators can change the ground reflectance if there is snow on the ground. Entering “**Yes**” in this field allows the weather file conditions to represent “Rain” and “Snow”; entering “**No**” in the field “turns off” the rain/snow indicators for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

IDF Example:

```
SizingPeriod:WeatherFileConditionType,
  Extreme Summer Weather Period for Design, !- Name
  SummerExtreme,                               !- Period Selection
  SummerDesignDay,                            !- Day Type
  No,                                         !- Use Weather File Daylight Saving Period

```

## 1.7.7 RunPeriod

The RunPeriod object describes the elements necessary to create a weather file simulation. Multiple run periods may be input. EnergyPlus accepts weather files in the special EnergyPlus weather format (described briefly below this document and in more detail in the Auxiliary Programs document). These files can describe Daylight Saving Time periods as well as holidays within their definitions. Note that the weather file also may contain design condition information, typical and extreme period information, ground temperatures based on air temperature calculations. The RunPeriod object allows the user to override the use of both the Daylight Saving Period (i.e. use

or ignore) and holidays that are embedded within the weather file. The object also describes the elements necessary to use a specially crafted (likely multiple year) weather file in a simulation. These kinds of weather files and simulations might be useful for matching utility periods or simulating several years of differing weather data. Leap days are required when using actual weather (see “Treat as Actual Weather” below), but will be processed and used during leap years when the days are present in the weather file and enabled in the weather file header. Note that when the weather is treated as non-actual, the leap day will be skipped if it is not present, resulting in incorrect day types for the remainder of the year. Further, the weather data interpolation for the first hour can also be specified to use Hour1 (natural) or Hour24 (considering warning up).

### 1.7.7.1 Inputs

#### 1.7.7.1.1 Field: Name

This optional field allows the RunPeriod to be named for output reporting. When left blank, the weather file location name is used. Note that the weather file location name will be appended to this name in tabular/summary reports.

#### 1.7.7.1.2 Field: Begin Month

This numeric field should contain the starting month number (1 = January, 2 = February, etc.) for the annual run period desired.

#### 1.7.7.1.3 Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

#### 1.7.7.1.4 Field: Begin Year

This optional numeric field may contain the beginning year for the range. If this field is specified along with the **Day of Week for Start Day**, the inputs are validated to make sure that the date is valid. If this field is not specified, then a year will be selected based upon other inputs (which, in the case of the day of the week, may be defaulted).

#### 1.7.7.1.5 Field: End Month

This numeric field should contain the ending month number (1 = January, 2 = February, etc.) for the annual run period desired.

#### 1.7.7.1.6 Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

#### 1.7.7.1.7 Field: End Year

This optional numeric field should contain the end year for the range. It is only allowed to be specified when the **Begin Year** is given and must be after the **Begin Year**. If it is not specified, it will be set to be the first occurrence of **End Month/End Day of Month** after the start date. Note that this could be several years after the start date (e.g. if the end date is specified as a leap day 2/29).

#### 1.7.7.1.8 Field: Day of Week for Start Day

This field allows the start day of the week to be specified. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) may be entered in this field. To clarify, this value will be used as the Start Day (type) for this run period and subsequent days will be implemented. If the field is blank, then the starting day type defaults to Sunday.

#### 1.7.7.1.9 Field: Use Weather File Holidays and Special Days

Weather files can contain holiday designations or other kinds of special days. These day types cause a corresponding day's schedule (see SCHEDULE definitions below) to be used during that day. This field should contain the word **Yes** if holidays or other special days indicated directly on the weather file should retain their "day type" or **No** if holidays or other special days on the weather file should be ignored. Reference the **RunPeriodControl:SpecialDays** object below to enter your own special days and holidays.

Note that a blank or null field in this field will indicate **Yes**.

#### 1.7.7.1.10 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

#### 1.7.7.1.11 Field: Apply Weekend Holiday Rule

In some countries (notably the US), when holidays fall on weekends, they are often observed on a weekday close to the holiday day. (Usually if the specific day falls on a Saturday, the observed day is Friday; if on a Sunday, the observed day is Monday). EnergyPlus will represent this custom using the value in this field. If the field is **Yes**, then specific date holidays that have a duration of one day, will be "observed" on the Monday after the day. (Specific day holidays are such as January 1 – a day-month combination). If the field is blank or **No**, then the holiday will be shown on the day-month as entered. As this option is listed at the RunPeriod, all applicable special days for the run will use the rule – there is no override for individual special days.

Note that a blank or null field in this field will indicate **No**.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: <https://www.energypplus.net/weather> have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

#### 1.7.7.1.12 Field: Use Weather File Rain Indicators

Weather files can contain "rain" indicators. (EPW field "Present Weather Codes" – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Entering "**Yes**" in this field allows the weather file conditions to represent "Rain"; entering "**No**"

in the field “turns off” the rain indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

#### 1.7.7.1.13 Field: Use Weather File Snow Indicators

Weather files can contain “snow” indicators. (EPW field “Snow Depth” > 0 indicates “Snow on the ground”). In turn, snow changes the reflectivity of the ground and cascades changes of this reflectivity. Entering “**Yes**” in this field allows the weather file conditions to represent “Snow”; entering “**No**” in the field “turns off” the snow indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

#### 1.7.7.1.14 Field: Treat Weather as Actual

This field determines how stringent date matching between this object and the weather file is. Though all EnergyPlus (EPW) weather files contain a year field, this data is not typically used. Specifying “**Yes**” in this field causes the program to look specifically for the begin date (i.e. Begin Month, Begin Day of Month, Begin Year) and for the end date (i.e. End Month, End Day of Month, End Year) and require that leap days be present for leap years.

#### 1.7.7.1.15 Field: First Hour Interpolation Starting Values

This field allows the user to choose which hour of data should be used for the first day interpolation. In general, EnergyPlus uses a warm-up period to achieve a periodic initial condition for simulation. After the warming up period, EnergyPlus sets the first day’s starting conditions the same as the end of that day. Therefore, Hour 24 is usually used for this type of annual simulations. However, there are other running scenarios where the user would like to examine the natural transition in the first hour, since the first day’s beginning and end weather condition usually do not match in a weather file—sometimes or even often, with large differences, e.g. in temperature, humidity, or wind conditions. This input field allows a user to choose a more suitable option based on the user’s specific simulation goals.

If the “**Hour1**” is selected for this field, the weather data interpolation during the first hour will be based on the weather data on Hour 1 of the simulation period. If the “**Hour24**” is selected, the interpolation during the first hour will be based on the Hour 1 and Hour 24 (now assumed this is the intended conditions from a successful warm-up cycling). The default value is “**Hour24**”. Note that this option only affects the first hour of the first day in the entire run period; the succeeding days in a run period would not be affected.

And, as shown in an IDF:

```
RunPeriod, ! Winter Simulation

---

## 1.7.8 RunPeriodControl:SpecialDays

For weather file run periods, special day run periods can be described. These will always be in effect for the selected days in the run period. Depending on the Use Special Days value in the RunPeriod:\* object(s), these can augment any special days included on the weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: <https://www.energyplus.net/weather> have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

### 1.7.8.1 Inputs

#### 1.7.8.1.1 Field: Name

This alpha field is the title for the special day period. It must be unique among all the special day period objects entered.

#### 1.7.8.1.2 Field: Start Date

This field is the starting date for the special day period. Dates in this field can be entered in several ways as shown in the accompanying table:

Table 1.9: Date Field Interpretation

Field Contents	Interpretation
< number > / < number >	Month / Day
< number > Month	Day and Month
Month < number >	Day and Month
< number > Weekday in Month	Numbered weekday of month
Last Weekday In Month	Last weekday of month

In the table, Month can be one of (January, February, March, April, May, June, July, August, September, October, November, December). Abbreviations of the first three characters are also valid.

In the table, Weekday can be one of (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday). Abbreviations of the first three characters are also valid.

### 1.7.8.1.3 Field: Duration

This numeric field specifies how long (number of days) the special day period lasts.

### 1.7.8.1.4 Field: Special Day Type

This alpha field designates the “day type” for schedule use during the special period. It must be one of (Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2).

An example in the IDF would be:

```
RunPeriodControl:SpecialDays, 'Presidents Day, 3rd Monday in February,1,Holiday;
RunPeriodControl:SpecialDays, Thanksgiving, 4th Thursday in November, 1,Holiday;
RunPeriodControl:SpecialDays, Halloween, 10/31, 1, Holiday;
RunPeriodControl:SpecialDays, Vacation, 5/1, 14, CustomDay1;
```

## 1.7.9 RunPeriodControl:DaylightSavingTime

Similar to a special day period, a daylight saving period may be entered to be applied to weather file run periods. These will always be in effect, regardless of the value entered on the **RunPeriod** object. Note that this period will always override any daylight saving period specified in a weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: <https://www.energyplus.net/weather> have neither special days specified nor daylight saving period.

**Note: For EnergyPlus Output:Variable and Output:Meter reporting, the time stamps are always in standard time. When daylight saving time is active, scheduled loads and controls will shift one hour relative to standard time.**

### 1.7.9.1 Inputs

#### 1.7.9.1.1 Field: Start Date

This is the starting date of the daylight saving period. Note that it can be entered in several formats as shown in Table 1.9. Date Field Interpretation.

#### 1.7.9.1.2 Field: End Date

This is the ending date of the daylight saving period. Note that it can be entered in several formats as shown in Table 1.9. Date Field Interpretation.

And in the IDF:

```
! U.S. Standard for Daylight Saving
RunPeriodControl:DaylightSavingTime,2nd Sunday in March, 1st Sunday in November; !2007
! Brazil standard
RunPeriodControl:DaylightSavingTime,1st Sunday in October, Last Sunday in February;
! European Standard
RunPeriodControl:DaylightSavingTime, Last Sunday in March, Last Sunday in October;
```

```
! Syria Standard
RunPeriodControl:DaylightSavingTime, 4/1, 10/1;
```

Of course, these could not all appear in the same IDF as only one DaylightSavingPeriod object per input file is allowed. More information on Daylight Saving Periods can be seen on the web at: <http://www.webexhibits.org/daylightsaving/>. The ASHRAE Handbook of Fundamentals [ASHRAE 2005] also contains information about daylight saving periods and their climatic information now includes start and end dates for many locations.

### 1.7.10 WeatherProperty:SkyTemperature

Sky Temperature, or radiative sky temperature, is internally calculated by EnergyPlus with an empirical model using sky cloudiness factors and current clear sky emissivity. For flexibility, the following object can be entered to override the entire internal sky temperature calculation from schedule import.

In particular, during Weather File Run Periods, the sky temperature is derived by the horizontal infrared radiation if presented in the weather file input by default. For flexibility, the field **Use Weather File Horizontal IR** can be set to “No” to ignore horizontal IR values from the weather file and always use the specified sky model for horizontal infrared radiation and sky temperature calculations.

By default, EnergyPlus calculates clear sky emissivity using Clark-Allen model. The following object can also be entered to adopt alternative sky emissivity calculation methods. Alternative methods of sky emissivity calculation include the calibrated forms of Berdahl & Martin, Brunt, and Idso model. Their algorithms are all described in the Engineering Reference document. Much of the literature describes the sky temperature as relative to water vapor pressure, drybulb or dewpoint temperature.

#### 1.7.10.1 Inputs

##### 1.7.10.1.1 Field: Name

This name references an existing design period (i.e., **SizingPeriod:DesignDay**, **SizingPeriod:WeatherFileDays** or **SizingPeriod:WeatherFileConditionType**) or run period (by name or blank for all run periods).

##### 1.7.10.1.2 Field: Calculation Type

Allowable entries here are: **ClarkAllen**, **Brunt**, **Idso**, **BerdahlMartin**, **ScheduleValue**, **DifferenceScheduleDryBulbValue**, or **DifferenceScheduleDewPointValue**.

In the case of **ScheduleValue**, **DifferenceScheduleDryBulbValue** and **DifferenceScheduleDewPointValue** the following field must specify a valid schedule name.

**ClarkAllen** – the clear sky emissivity are calculated using Clark and Allen model. This is the default model to calculate clear sky emissivity.

**Brunt** – the clear sky emissivity are calculated using Brunt model.

**Idso** – the clear sky emissivity are calculated using Idso model.

**BerdahlMartin** – the clear sky emissivity are calculated using Berdahl & Martin model.

**ScheduleValue** – the values in the schedule are used as the sky temperature.

**DifferenceScheduleDryBulbValue** – the values in the schedule are *subtracted* from the drybulb temperature value (+values would then be less than the drybulb temperature, -values would then be greater than the drybulb temperature) for the resulting sky temperature value.

**DifferenceScheduleDewPointValue** – the values in the schedule are *subtracted* from the dewpoint temperature value (+values would then be less than the dewpoint temperature, -values would then be greater than the dewpoint temperature) for the resulting sky temperature value.

#### 1.7.10.1.3 Field: ScheduleName

This field specifies a schedule name to accomplish the sky temperature calculation from the previous field. A Schedule:Day:\*

- (i.e., Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day>List)

should be specified if the name in the name field matches a SizingPeriod:DesignDay object. If the name is one of the weather file period specifications (i.e. matches a SizingPeriod:WeatherFileDays, SizingPeriod:WeatherFileConditionType or RunPeriod), then the schedule name must match a full year schedule (i.e. Schedule:Year, Schedule:Compact, Schedule:File, or Schedule:Constant).

#### 1.7.10.1.4 Field: Use Weather File Horizontal IR

This field specifies whether or not to use the horizontal infrared radiation values from weather files if presented. The field is default to be true. If yes or blank, and the values are presented in weather file, EnergyPlus uses the values from weather file for weather calculations, otherwise it uses the specified sky model to calculate the values. If no, it always uses the specified sky model and ignores the horizontal IR values from the weather file. For **Calculation Type = ScheduleValue**, **ScheduleValue** or **DifferenceScheduleDewPointValue**, this field is ignored and the scheduled values are used. If this field is set to **No** but no specific sky model is declared in the field **Calculation Type**, the default sky model **ClarkAllen** is used.

An example of IDF usage (with DesignDay):

```

SizingPeriod:DesignDay,
  DENVER_STAPLETON Ann Clg 1% Sky Temperature modifier, !- Name
  32.6,           !- Maximum Dry-Bulb Temperature {C}
  15.2,           !- Daily Temperature Range {deltaC}
  15.5,           !- Humidity Indicating Conditions at Maximum Dry-Bulb
  83411.,         !- Barometric Pressure {Pa}
  4,              !- Wind Speed {m/s}
  120,             !- Wind Direction {deg}
  1.00,            !- Sky Clearness
  0,              !- Rain Indicator
  0,              !- Snow Indicator
  25,             !- Day of Month
  7,              !- Month
  SummerDesignDay, !- Day Type
  0,              !- Daylight Saving Time Indicator
  WetBulb,        !- Humidity Indicating Type
  ,               !- Relative Humidity Day Schedule Name
  deltaschedule, !- Dry-Bulb Temperature Range Modifier Type
  temp range deltas; !- Dry-Bulb Temperature Range Modifier Schedule Name

WeatherProperty:SkyTemperature,
  DENVER_STAPLETON Ann Clg 1% Sky Temperature modifier, !- Name
  ScheduleValue,   !- Calculation Type
  DaySchedule5;    !- Schedule Name

Schedule:Day:Interval,
  DaySchedule5,    !- Name
  Temperature,    !- Schedule Type Limits Name
  Yes,             !- Interpolate to Timestep
  until: 24:00,    !- Time 1
  5;              !- Value Until Time 1

```

Another example of IDF usage:

```

WeatherProperty:SkyTemperature,
,
UseBerdahlMartinModel,      !- Calculation Type
,
No;                         !- Use Weather File Horizontal IR

```

---

### 1.7.11 Site:WeatherStation

The Site:WeatherStation object is used to specify the measurement conditions for the climatic data listed in the weather file. These conditions indicate the height above ground of the air temperature sensor, the height above ground of the wind speed sensor, as well as coefficients that describe the wind speed profile due to the terrain surrounding the weather station. There are necessary correlations between the entries for this object and some entries in the Building object, specifically the **Terrain** field.

Weather stations throughout the world (ref: WMO – World Meteorological Organization) take their measurements at standard conditions:

- Air temperature is measured at approximately 1.5 m above ground
- Wind speed is measured at 10 m above ground
- Weather station is in a flat, open field with little protection from the wind.

When using weather data from standard sources (e.g., TMY2, IWEC, TMY, or ASHRAE design day data), it is not necessary to use the **Site:WeatherStation** object. However, if you are using custom weather data or real-time weather data, you may need to read and understand the concepts in the **Site:WeatherStation** object.

The measurement conditions at the weather station (i.e., the weather file) are used by EnergyPlus in conjunction with the *Terrain* field of the **Building** object, or optionally with the **Site:HeightVariation** object (see below), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The algorithms for this calculation are in the Engineering Reference.

The **Site:WeatherStation** object is useful when working with a custom weather file that includes data that were not measured at the WMO standard conditions. For example, the weather data could be measured on site, or on the roof top of a nearby building. The wind speed profile coefficients can be estimated from the table below or calculated beforehand using more sophisticated techniques such as CFD modeling of the weather station terrain.

Table 1.10: Wind Speed Profile Coefficients (ASHRAE Fundamentals 2005).

Terrain Description	Exponent	Boundary Layer Thickness (m)
Flat, open country	0.14	270
Rough, wooded country	0.22	370
Towns and cities	0.33	460

Table 1.10: Wind Speed Profile Coefficients (ASHRAE Fundamentals 2005).

Terrain Description	Exponent	Boundary Layer Thickness (m)
Ocean	0.10	210
Urban, industrial, forest	0.22	370

If the **Site:WeatherStation** object is omitted from the input file, the WMO standard measurement conditions are assumed.

### 1.7.11.1 Inputs

#### 1.7.11.1.1 Field: Wind Sensor Height Above Ground

The height [m] above ground for the wind speed sensor.

#### 1.7.11.1.2 Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the weather station. The exponent can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

#### 1.7.11.1.3 Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the weather station. The boundary layer can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

#### 1.7.11.1.4 Field: Air Temperature Sensor Height Above Ground

The height [m] above ground for the air temperature sensor.

For example, if you are using weather data measured on the top of your building, you should set the *Wind Sensor Height Above Ground* and the *Air Temperature Sensor Height Above Ground* to equal the height of your building (say 30 m). The *Wind Speed Profile Exponent* and *Wind Speed Profile Boundary Layer Thickness* should be set to match the values associated with the *Terrain* field of the **Building** object, or the equivalent fields of the **Site:HeightVariation** object.

Or, in IDF terms, with a building in a town or city:

```
Site:WeatherStation,
 30,    !- Wind Sensor Height Above Ground {m}
 0.33,   !- Wind Speed Profile Exponent {}
 460,   !- Wind Speed Profile Boundary Layer Thickness {m}
 30;    !- Air Temperature Sensor Height Above Ground {m}
```

This would change if you had a different wind speed profile exponent or wind speed profile boundary layer thickness at your site.

### 1.7.12 Site:HeightVariation

The **Site:HeightVariation** object is used to specify the local variation in atmospheric properties at the site and should be used only if you require advanced control over the height-dependent variations

for wind speed and temperature. The coefficients set by this object are used by EnergyPlus, in conjunction with the **Site:WeatherStation** object (see above), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The local outdoor air temperature and wind speed are calculated separately for all zones and surfaces, and optionally for outdoor air nodes for which a height has been specified (see **OutdoorAir:Node** object). With the default inputs, wind speed falls significantly at heights lower than the weather station measurement height, and temperature increases slightly. The algorithms for this calculation are in the Engineering Reference. There are necessary correlations between the entries for this object and some entries in the **Building** object, specifically the **Terrain** field.

Table 1.11: Atmospheric Variables at Two Different Heights Above Ground Level.

Variable	1.5 m	284 m	Absolute Diff	Percent Diff
Air Temperature	15°C	13.15°C	1.85°C	12.3%
Barometric Pressure	101,325 Pa	97,960 Pa	3,365 Pa	3.3%
Wind Speed	2.46 m/s	7.75 m/s	5.29 m/s	215%

Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if the wind speed profile fields are left blank. The wind speed profile coefficients can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques such as CFD modeling of the site terrain.

### 1.7.12.1 Inputs

#### 1.7.12.1.1 Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the site. The exponent can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank. This field can be set to zero to turn off all wind dependence on height.

#### 1.7.12.1.2 Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the site. The boundary layer can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank.

#### 1.7.12.1.3 Field: Air Temperature Gradient Coefficient

The air temperature gradient coefficient [K/m] is a research option that allows the user to control the variation in outdoor air temperature as a function of height above ground. The real physical value is 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height.

Note that the *Air Temperature Sensor Height* in the **Site:WeatherStation** object should also be set to zero in order to force the local outdoor air temperatures to match the weather file outdoor air temperature. This change is required because the **Site:WeatherStation** object assumes an air temperature gradient of 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height.

```
Site:HeightVariation,
 0.22,      !- Wind Speed Profile Exponent
 370,      !- Wind Speed Profile Boundary Layer Thickness {m}
 0.0065;   !- Air Temperature Gradient Coefficient {deltaC/m}
```

---

### 1.7.13 Site:GroundTemperature:BuildingSurface

Ground temperatures are used for the ground heat transfer model. There can be only one ground temperature object included, and it is used as the outside surface temperature for all surfaces with Outside Boundary Condition = Ground. The object is options if you have no surfaces with ground contact. The outside surface temperature for individual surfaces can be specified using the OtherSideCoefficients (ref: [SurfaceProperty:OtherSideCoefficients](#)) object that allows Toutside to be set with a schedule. This permits using any number of different outside face temperatures in addition to the ground temperature.

**Caution:** The “undisturbed” ground temperatures calculated by the weather converter should not be used in building losses but are appropriate to be used in the **Site:GroundTemperature:Shallow** and **Site:GroundTemperature:Deep** objects. The reasoning (for building losses) is that these values are too extreme for the soil under a conditioned building. For best results, use the Slab or Basement program described in this document to calculate custom monthly average ground temperatures (see the Ground Heat Transfer section). This is especially important for residential applications and very small buildings. If one of these ground temperature preprocessors is not used, for typical commercial buildings in the USA, a reasonable default value is 2 °C less than the average indoor space temperature.

More information about determining appropriate ground temperatures is given in the Auxiliary Programs document.

#### 1.7.13.1 Inputs

##### 1.7.13.1.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January = 1<sup>st</sup> field, February = 2<sup>nd</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:BuildingSurface ,19,20,20,20,20,20,20,20,20,20,20;
```

---

### 1.7.14 Site:GroundTemperature:Shallow

**Site:GroundTemperature:Shallow** are used by the Surface Ground Heat Exchanger (i.e. object: [GroundHeatExchanger:Surface](#)). Only one shallow ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the .5 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions of the building location.

This object may be used for objects requiring “undisturbed” ground temperatures. In these instances, the “name” input field is not required.

### 1.7.14.1 Inputs

#### 1.7.14.1.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly surface ground temperature (degrees Celsius) used for the indicated month (January = 1<sup>st</sup> field, February = 2<sup>nd</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:Shallow,4,4,6,6,10,10,15,15,14,14,8,8;
```

### 1.7.15 Site:GroundTemperature:Deep

Site:GroundTemperature:Deep are used by the Pond Ground Heat Exchanger object (i.e. object: [GroundHeatExchanger:Pond](#)). Only one deep ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the 4 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions or special knowledge of the building location.

This object may be used for objects requiring “undisturbed” ground temperatures. In these instances, the “name” input field is not required.

### 1.7.15.1 Inputs

#### 1.7.15.1.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly deep ground temperature (degrees Celsius) used for the indicated month (January = 1<sup>st</sup> field, February = 2<sup>nd</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:Deep, 16,16,16,16,16,16,16,16,16,16,16,16;
```

### 1.7.16 Site:GroundTemperature:Undisturbed:FiniteDifference

Site:GroundTemperature:Undisturbed:FiniteDifference may be used by all objects requiring “undisturbed” ground temperatures. The object uses a 1D finite difference heat transfer model which uses the weather file to obtain surface boundary conditions. An annual simulation is run on the model during it’s initialization until the annual ground temperature profile has reached steady periodic behavior. Once steady periodic behavior is reached, the ground temperatures are cached for retrieval during the rest of the simulation.

### 1.7.16.1 Inputs

#### 1.7.16.1.1 Field: Soil Thermal Conductivity

The thermal conductivity of the soil, in W/m-K.

#### 1.7.16.1.2 Field: Soil Density

The bulk density of the soil, in kg/m<sup>3</sup>.

#### 1.7.16.1.3 Field: Soil Specific Heat

The specific heat of dry soil, in J/kg-K.

#### 1.7.16.1.4 Field: Soil Moisture Content Volume Fraction

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

#### 1.7.16.1.5 Field: Soil Moisture Content Volume Fraction at Saturation

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

#### 1.7.16.1.6 Field: Evapotranspiration Ground Cover Parameter

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth).

An IDF example:

```
Site:GroundTemperature:Undisturbed:FiniteDifference,
  FDTemps, !- Name of object
  1.08,    !- Soil Thermal Conductivity {W/m-K}
  962,     !- Soil Density {kg/m3}
  2576,    !- Soil Specific Heat {J/kg-K}
  30,      !- Soil Moisture Content Volume Fraction {percent}
  50,      !- Soil Moisture Content Volume Fraction at Saturation {percent}
  0.408;   !- Evapotranspiration Ground Cover Parameter
```

### 1.7.17 Site:GroundTemperature:Undisturbed:KusudaAchenbach

Site:GroundTemperature:Undisturbed:KusudaAchenbach may be used by all objects requiring “undisturbed” ground temperatures. It provides an undisturbed ground temperature based on the correlation developed by Kusuda T. and P. Achenbach. 1965. The correlation uses three parameters for ground temperature at the surface to define a correlation for undisturbed ground temperatures as a function of depth and time. If one thinks of the ground temperature for a given depth as a sinusoid, the average ground temperature, amplitude (average difference between maximum ground temperature and minimum ground temperature), and the phase shift (day of minimum surface temperature) are all required to define the correlation.

If the parameters are left blank they can be autocalculated by including soil surface temperatures in the input using the **Site:GroundTemperature:Shallow** object. They can also be calculated by using the CalcSoilSurfTemp preprocessor.

Kusuda, T. and P.R. Achenbach. 1965. ‘Earth Temperatures and Thermal Diffusivity at Selected Stations in the United States.’ *ASHRAE Transactions*. 71(1): 61-74.

### 1.7.17.1 Field: Soil Thermal Conductivity

The thermal conductivity of the soil, in W/m-K.

### 1.7.17.2 Field: Soil Density

The bulk density of the soil, in kg/m3.

### 1.7.17.3 Field: Soil Specific Heat

The specific heat of dry soil, in J/kg-K.

### 1.7.17.4 Field: Average Annual Ground Surface Temperature

This is the average ground surface temperature throughout the entire year, in °C.

### 1.7.17.5 Field: Average Amplitude of Annual Ground Surface Temperature

This is the average amplitude of the ground surface temperature, in °C.

### 1.7.17.6 Field: Phase Shift of Minimum Surface Temperature

This is day of the year which has the lowest ground surface temperature.

An IDF example:

```
Site:GroundTemperature:Undisturbed:KusudaAchenbach,
  KATemps,      !- Name of object
  1.08,         !- Soil Thermal Conductivity {W/m-K}
  962,          !- Soil Density {kg/m3}
  2576,         !- Soil Specific Heat {J/kg-K}
  15.5,         !- Average Soil Surface Temperature {C}
  12.0,         !- Average Amplitude of Surface Temperature {deltaC}
  21;           !- Phase Shift of Minimum Surface Temperature {days}
```

---

## 1.7.18 Site:GroundTemperature:Undisturbed:Xing

Site:GroundTemperature:Undisturbed:Xing may be used by all objects requiring “undisturbed” ground temperatures. It provides an undisturbed ground temperature based on the correlation developed by Xing, 2014. The correlation is a 5 parameter, 2 harmonic model based on the work of Lord Kelvin (Thomson, 1862). The average soil surface temperature and two sets of surface temperature amplitude and phase shift must be provided. Parameters for 4000+ international locations can be found in Xing, 2014.

Thomson, W. 1862. ‘On the Reduction of Observations of Underground Temperature, with applications to Professor Forbes’ Edinburgh Observations and the continued Calton Hill Series.’ Proceedings of the Royal Society of Edinburgh. IV: 342-346.

Xing, L. 2014. Estimations of Undisturbed Ground Temperatures using Numerical and Analytical Modeling. Ph.D. Diss. Oklahoma State University, Stillwater, OK.

### 1.7.18.1 Inputs

#### 1.7.18.1.1 Field: Soil Thermal Conductivity

The thermal conductivity of the soil, in W/m-K.

**1.7.18.1.2 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

**1.7.18.1.3 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K.

**1.7.18.1.4 Field: Average Soil Surface Temperature**

The average annual surface temperature of the soil, in deg C.

**1.7.18.1.5 Field: Soil Surface Temperature Amplitude 1**

First soil surface temperature amplitude parameter, in deg C.

**1.7.18.1.6 Field: Soil Surface Temperature Amplitude 2**

Second soil surface temperature amplitude parameter, in deg C.

**1.7.18.1.7 Field: Phase Shift of Surface Temperature Amplitude 1**

Phase shift of surface temperature amplitude 1, in days.

**1.7.18.1.8 Field: Phase Shift of Surface Temperature Amplitude 2**

Phase shift of surface temperature amplitude 2, in days.

An IDF example:

```
Site:GroundTemperature:Undisturbed:Xing,
Chicago-OHare,!- Name of object
1.08,          !- Soil Thermal Conductivity {W/m-K}
962,           !- Soil Density {kg/m3}
2576,          !- Soil Specific Heat {J/kg-K}
11.1,          !- Average Soil Surface Temperature {C}
13.4,          !- Soil Surface Temperature Amplitude 1 {deltaC}
0.7,           !- Soil Surface Temperature Amplitude 2 {deltaC}
25,            !- Phase Shift of Temperature Amplitude 1 {days}
30;            !- Phase Shift of Temperature Amplitude 2 {days}
```

**1.7.19 Site:GroundDomain:Slab**

This section documents the input object used to simulate ground coupled heat transfer with horizontal building surfaces within EnergyPlus. Horizontal ground surfaces within EnergyPlus interact with the Site:GroundDomain object by utilizing the [SurfaceProperty:OtherSideConditionsModel](#) object. By utilizing this object, multiple horizontal surfaces can be coupled to the same Site:GroundDomain object. Each horizontal surface may also have its unique ground domain, however, runtime will be adversely affected.

Generally, there are two scenarios which Site:GroundDomain is equipped to model: in-grade slabs and on-grade slabs.

The in-grade slab option can be used to simulate situations when the upper slab surface is near the ground surface level. For this situation, slab's upper surface must interact with the zone via an OSCM boundary. Due to this, the FloorConstruction object for the zone floor must include a thin layer of the upper floor material. Horizontal and vertical insulation are modeled by the GroundDomain in this scenario. Horizontal insulation can be modeled as covering the full horizontal

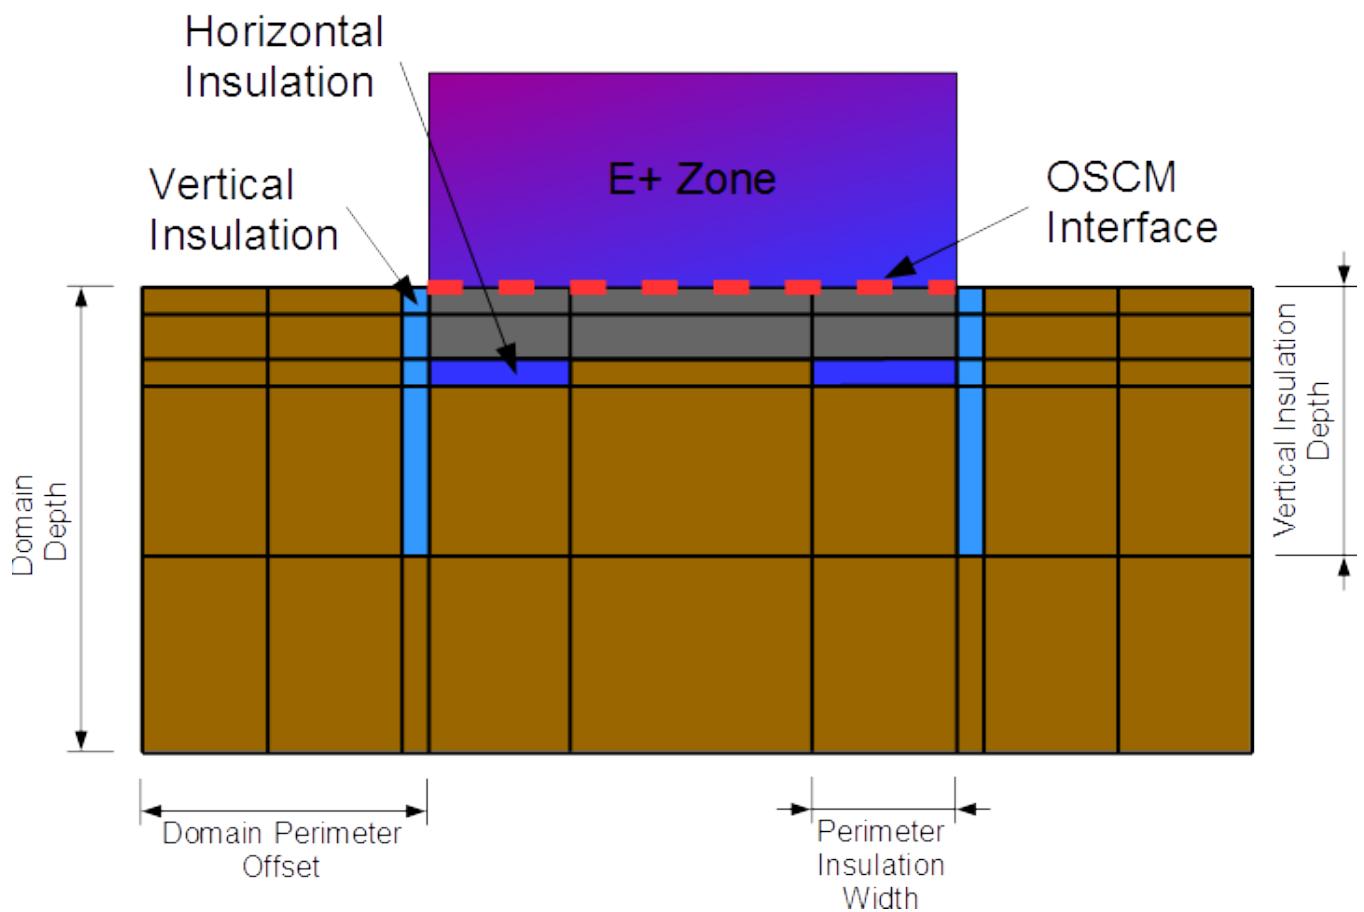

Figure 1.7: In-grade configuration.

surface, or it can be limited to the perimeter regions only. In the latter case, the perimeter insulation width must be specified.

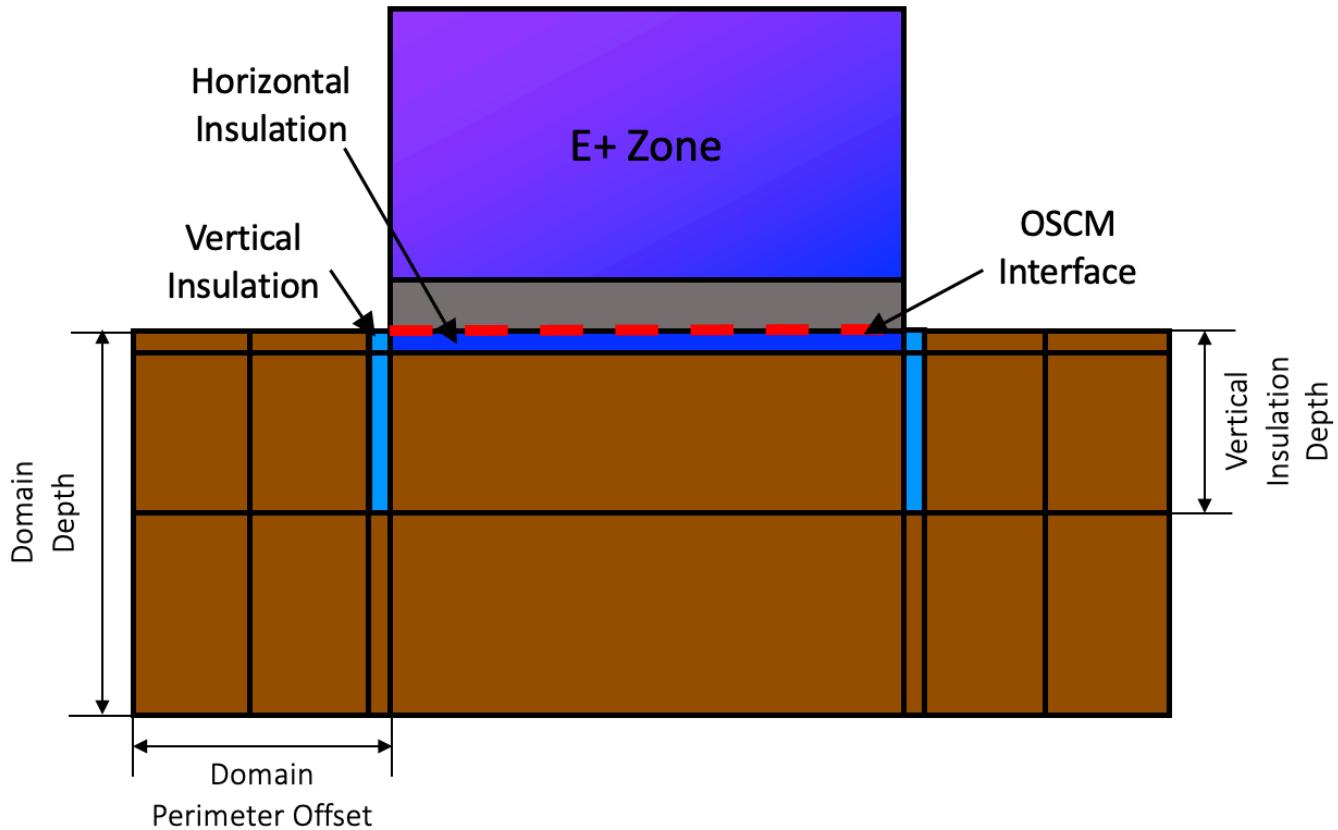

Figure 1.8: On-grade configuration

The on-grade slab option can be used to simulate situations when the lower slab surface is near the ground surface level. In this situation, the entire floor must be included within the floor construction object. Vertical insulation is modeled by the `GroundDomain` in this scenario. Horizontal insulation can only be modeled as covering the full horizontal surface.

### 1.7.19.1 Inputs

#### 1.7.19.1.1 Field: Name

Alpha field used as a unique identifier for each ground domain.

#### 1.7.19.1.2 Field: Ground Domain Depth

Numeric field used to determine the depth of the simulation domain, in meters.

#### 1.7.19.1.3 Field: Aspect Ratio

Numeric field, which is the ratio of slab length to width and is used to determine the aspect ratio of the slab. This field along with the total slab floor area, which is taken as the combination of all surfaces connected to the floor `OtherSideConditionsModel`, are used to determine the size and shape of the ground domain. Any given aspect ratio and its inverse should produce identical results. i.e.  $AR = 2$  equals  $AR = 0.5$ . This field has units of meters/meters.

**1.7.19.1.4 Field: Perimeter Offset**

Numeric field used to determine the distance from the slab perimeter to the domain perimeter, in meters.

**1.7.19.1.5 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

**1.7.19.1.6 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

**1.7.19.1.7 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

**1.7.19.1.8 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

**1.7.19.1.9 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

**1.7.19.1.10 Field: Type of Undisturbed Ground Temperature Object**

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

**1.7.19.1.11 Field: Name of Undisturbed Ground Temperature Object**

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

**1.7.19.1.12 Field: Evapotranspiration Ground Cover Parameter**

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth).

**1.7.19.1.13 Field: Slab Boundary Condition Model Name**

This is the name of the other side boundary condition model used.

**1.7.19.1.14 Field: Slab Location**

Alpha field indicates whether the slab is in-grade (top surface level with ground surface) or on-grade (bottoms surface level with ground surface). Options include “ONGRADE” and “INGRADE”.

**1.7.19.1.15 Field: Slab Material Name**

Name of the material object representing the slab material. Only applicable to in-grade situations.

#### 1.7.19.1.16 Field: Horizontal Insulation

Alpha field indicates whether horizontal insulation is present. Options include “YES” and “NO”. Only applicable to in-grade situations.

#### 1.7.19.1.17 Field: Horizontal Insulation Material Name

This alpha field is the name of a material object representing the horizontal slab insulation. It should be noted that the material listed here cannot be a “no mass” material ([Material:NoMass](#)) that is defined by R-Value only but should be defined as a regular material with an actual thickness. This optional argument is only required if horizontal insulation is present.

#### 1.7.19.1.18 Field: Horizontal Insulation Extents

Alpha field indicates whether the horizontal slab insulation extends to cover the full horizontal area of the slab, or only covers the slab perimeter. Optional argument only required if horizontal insulation is present. Options include “FULL” and “PERIMETER”.

#### 1.7.19.1.19 Field: Perimeter Insulation Width

Numeric field indicating the width of the perimeter insulation measured from the slab edge. Valid range from > 0 to < half of smallest slab width.

#### 1.7.19.1.20 Field: Vertical Insulation

Alpha field indicates whether vertical insulation is present. Options include “YES” and “NO”.

#### 1.7.19.1.21 Field: Vertical Insulation Name

This alpha field is the name of a material object representing the vertical slab insulation. It should be noted that the material listed here cannot be a “no mass” material ([Material:NoMass](#)) that is defined by R-Value only but should be defined as a regular material with an actual thickness. This optional argument is only required if vertical insulation is present.

#### 1.7.19.1.22 Field: Vertical Insulation Depth

Numeric field indicates the depth measured in meters from the ground surface to which the vertical perimeter insulation extends. Valid range from > Slab Thickness to < Domain Depth.

#### 1.7.19.1.23 Field: Simulation Timestep

Alpha field indicating whether the domain will update temperatures at each zone timestep, or at hourly intervals. Options include “timestep” and “hourly”.

#### 1.7.19.1.24 Field: Geometric Mesh Coefficient

This numeric field represents the compression of cell distribution A value in this field equal to 1 would result in a uniform distribution, while a value of 2 would provide a highly skewed distribution. Values for this field should be limited from 1.0 to 2.0. If this field is omitted, the default value is 1.6.

### 1.7.19.1.25 Field: Mesh Density Parameter

This numeric integer field represents the number of cells to be placed between any two “domain partitions” during mesh development. A domain partition may be thought of as a slab edge or insulation edge. Once these components are laid out in the domain, this field number of cells are placed between the partitions. If this field is omitted, the default value is 6.

An IDF example of an in-grade slab.

### 1.7.19.2 Outputs

The following output variables are available.

- Zone, Average, Zone Coupled Surface Heat Flux [W/m<sup>2</sup>]
- Zone, Average, Zone Coupled Surface Temperature [C]

### 1.7.19.2.1 Zone Coupled Surface Heat Flux [W/m<sup>2</sup>]

This is the value of the heat flux provided to the GroundDomain as a boundary condition. This is calculated by taking the average heat flux of all surfaces coupled to the domain's SurfaceProperty:OtherSideConditionsModel model.

### 1.7.19.2.2 Zone Coupled Surface Temperature [C]

This is the value of the SurfaceProperty:OtherSideConditionsModel surface temperature. This is the temperature provided to the ground coupled surfaces as an outside boundary condition.

## 1.7.20 Site:GroundDomain:Basement

This section documents the input object used to simulate ground coupled heat transfer with underground zones within EnergyPlus. Zone surfaces within EnergyPlus interact with the Site:GroundDomain:Basement object by utilizing the **SurfaceProperty:OtherSideConditionsModel** object. Two separate OSCM are required for the basement vertical and horizontal surfaces. Vertical wall surfaces will interact with the first OSCM while the horizontal floor surface will interact with the second OSCM. Basement floor and wall surfaces are constructed normally by using the **BuildingSurface:Detailed** object, with the outside boundary condition being the OtherSideConditionsModel for the basement floor or wall. The outside surface of the wall being the interface between the ground domain and the EnergyPlus zone. Horizontal and vertical ground insulation are simulated by the ground domain, and therefore should not be included in the wall and floor construction objects.

### 1.7.20.1 Inputs

#### 1.7.20.1.1 Field: Name

Alpha field used as a unique identifier for each basement domain. Multiple basements domains can be simulated simultaneously, however, each domain must have a unique name. Additionally, despite the ability to simulate multiple domains simultaneously, these domains do not interact with

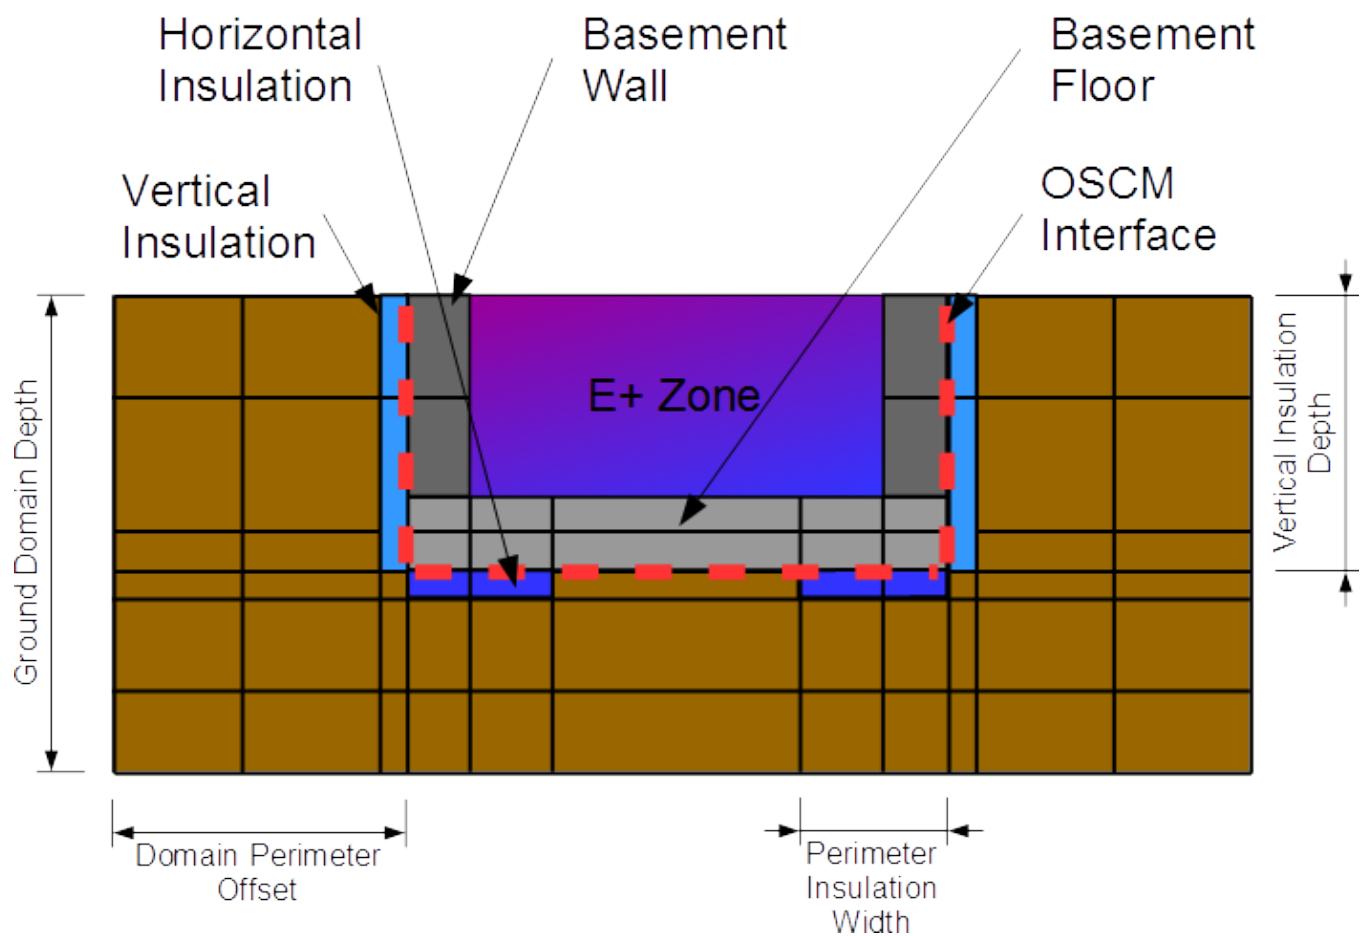

Figure 1.9: Basement Configuration

each other and are treated as independent domains with boundary conditions given by the model parameters below.

#### **1.7.20.1.2 Field: Ground Domain Depth**

Numeric field used to determine the depth of the simulation domain, in meters. A value of 10 meters is the default.

#### **1.7.20.1.3 Field: Aspect Ratio**

Numeric field, which is the ratio of basement length to width, used to determine the aspect ratio of the basement. This field along with the total basement floor area, which is taken as the combination of all surfaces connected to the floor OtherSideConditionsModel, are used to determine the size and shape of the basement domain. Aspect ratios and the inverse of aspect ratios should produce identical results. i.e. AR = 2 equals AR = 0.5. This field has units of meters/meters.

#### **1.7.20.1.4 Field: Domain Perimeter Offset**

Numeric field used to determine the distance from the basement perimeter to the domain perimeter, in meters. A value of 5 is default.

#### **1.7.20.1.5 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

#### **1.7.20.1.6 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

#### **1.7.20.1.7 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

#### **1.7.20.1.8 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

#### **1.7.20.1.9 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

#### **1.7.20.1.10 Field: Type of Undisturbed Ground Temperature Object**

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

#### **1.7.20.1.11 Field: Name of Undisturbed Ground Temperature Object**

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

#### 1.7.20.1.12 Field: Evapotranspiration Ground Cover Parameter

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth). Model can be sensitive to variations in this parameter, especially in dry climates.

#### 1.7.20.1.13 Field: Basement Floor Boundary Condition Model Name

This is the name of the other side boundary condition model used for the basement floor surface.

#### 1.7.20.1.14 Field: Horizontal Insulation

Alpha field indicates whether horizontal insulation is present. Options include “YES” and “NO”.

#### 1.7.20.1.15 Field: Horizontal Insulation Name

This alpha field is the name of a material object representing the horizontal underfloor basement insulation. It should be noted that the material listed here cannot be a “no mass” material ([Material:NoMass](#)) that is defined by R-Value only but should be defined as a regular material with an actual thickness. This optional argument is only required if horizontal insulation is present.

#### 1.7.20.1.16 Field: Horizontal Insulation Extents

Alpha field indicates whether the horizontal underfloor insulation extends to cover the full horizontal area of the basement floor, or only covers the basement floor perimeter. Optional argument only required if horizontal insulation is present. Options include “FULL” and “PERIMETER”.

#### 1.7.20.1.17 Field: Perimeter Insulation Width

Numeric field indicating the width of the perimeter insulation measured from the basement floor edge. Valid range from  $> 0$  to  $<$  half of smallest basement floor width.

#### 1.7.20.1.18 Field: Basement Depth

Depth of basement floor surface referenced from the ground surface, in meters. This domain should be the distance from the ground surface down to the basement floor surface. In cases where the ground surface is below the main above-ground building level, a separate wall surface should be employed between the basement walls and the main level walls.

#### 1.7.20.1.19 Field: Basement Wall Boundary Condition Model Name

Name of the other side condition boundary model used for the basement walls.

#### 1.7.20.1.20 Field: Vertical Insulation

Alpha field indicates whether vertical insulation is present. Options include “YES” and “NO”.

#### 1.7.20.1.21 Field: Vertical Insulation Name

This alpha field is the name of a material object representing the vertical basement insulation. It should be noted that the material listed here cannot be a “no mass” material ([Material:NoMass](#)) that is defined by R-Value only but should be defined as a regular material with an actual thickness. This optional argument is only required if vertical insulation is present.

#### 1.7.20.1.22 Field: Vertical Insulation Depth

Numeric field indicates the depth measured in meters from the ground surface to which the vertical perimeter insulation extends. Valid range from  $> 0$  to  $<$  Basement Depth.

#### 1.7.20.1.23 Field: Simulation Timestep

Alpha field indicating whether the domain will update temperatures at each zone timestep, or at hourly intervals. Options include “timestep” and “hourly”.

#### 1.7.20.1.24 Mesh Density Parameter

Integer field indicating the density of the finite difference ground domain cells between the basement and the far field boundaries. Default value is 4. Total number of ground domain cells, insulation cells, and ground surface cells are indicated as outputs to the eio file.

### 1.7.20.2 Outputs

The following output variables are available.

- Wall Interface Heat Flux
- Wall Interface Temperature
- Floor Interface Heat Flux
- Floor Interface Temperature

#### 1.7.20.2.1 Wall Interface Heat Flux [W/m<sup>2</sup>]

This is the value of the heat flux provided to ground domain as a boundary condition for the basement walls. Should be equal to the basement wall outside heat flux.

#### 1.7.20.2.2 Wall Interface Temperature [C]

This is the value of the SurfaceProperty:OtherSideConditionsModel surface temperature. This is the temperature provided to the basement wall surfaces as an outside boundary condition.

#### 1.7.20.2.3 Floor Interface Heat Flux [W/m<sup>2</sup>]

This is the value of the heat flux provided to ground domain as a boundary condition for the basement floor. Should be equal to the basement floor outside heat flux.

#### 1.7.20.2.4 Floor Interface Temperature [C]

This is the value of the SurfaceProperty:OtherSideConditionsModel surface temperature. This is the temperature provided to the ground coupled floor surfaces as an outside boundary condition.

## 1.7.21 Site:GroundTemperature:FCfactorMethod

Site:GroundTemperature:FCfactorMethod is used only by the underground walls or slabs-on-grade or underground floors defined with C-factor ([Construction:CfactorUndergroundWall](#)) and F-factor ([Construction:FfactorGroundFloor](#)) method for code compliance calculations where detailed construction layers are unknown. Only one such ground temperature object can be included. The monthly ground temperatures for this object are close to the monthly outside air temperatures delayed by three months. If user does not input this object in the IDF file, it will be defaulted to the 0.5m set of monthly ground temperatures from the weather file if they are available. Entering these will also overwrite any ground temperatures from the weather file in the F and C factor usage. If neither is available, an error will result.

### 1.7.21.1 Inputs

#### 1.7.21.1.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January = 1<sup>st</sup> field, February = 2<sup>nd</sup> field, etc.)

And, the IDF example:

---

```
Site:GroundTemperature:FCfactorMethod, 9.5, 3.5, -0.7, -1.7, -0.6, 3.6, 9.3, 14, 18.2, 22.7, 21.2, 16.8;
```

---

## 1.7.22 Site:GroundReflectance

Ground reflectance values are used to calculate the ground reflected solar amount. This fractional amount (entered monthly) is used in this equation:

$$\text{GroundReflectedSolar} = (\text{BeamSolar} \cdot \cos(\text{SunZenithAngle}) + \text{DiffuseSolar}) \cdot \text{GroundReflectance} \quad (1.7)$$

Of course, the Ground Reflected Solar is never allowed to be negative. The ground reflectance can be further modified when snow is on the ground by the Snow Ground Reflectance Modifier. To use no ground reflected solar in your simulation, enter 0.0 for each month.

### 1.7.22.1 Inputs

#### 1.7.22.1.1 Field: Month Average Ground Reflectance(s) – 12 fields in all

Each numeric field is the monthly average reflectivity of the ground used for the indicated month (January = 1<sup>st</sup> field, February = 2<sup>nd</sup> field, etc.)

And use in an IDF:

```
Site:GroundReflectance,
0.600, !January Ground Reflectance
0.600, !February Ground Reflectance
0.400, !March Ground Reflectance
0.300, !April Ground Reflectance
0.200, !May Ground Reflectance
0.200, !June Ground Reflectance
0.200, !July Ground Reflectance
0.200, !August Ground Reflectance
0.200, !September Ground Reflectance
0.200, !October Ground Reflectance
0.300, !November Ground Reflectance
0.400; !December Ground Reflectance
```

## 1.7.23 Site:GroundReflectance:SnowModifier

It is generally accepted that snow resident on the ground increases the basic ground reflectance. EnergyPlus allows the user control over the snow ground reflectance for both “normal ground reflected solar” calculations (see above) and snow ground reflected solar modified for daylighting. These are entered under this object and both default to 1 (same as normal ground reflectance – no special case for snow which is a conservative approach).

### 1.7.23.1 Inputs

#### 1.7.23.1.1 Field: Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{GroundReflectance}_{\text{used}} = \text{GroundReflectance} \cdot \text{Modifier}_{\text{Snow}} \quad (1.8)$$

The actual Ground Reflectance is limited to [0.0,1.0].

#### 1.7.23.1.2 Field: Daylighting Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{DaylightingGroundReflectance}_{\text{used}} = \text{GroundReflectance} \cdot \text{Modifier}_{\text{Snow}} \quad (1.9)$$

The actual Ground Reflectance is limited to [0.0,1.0].

An IDF example:

```
Site:GroundReflectance:SnowModifier,
  1.0;      !- Ground Reflected Solar Modifier
```

Outputs will show both the inputs from the above object as well as monthly values for both Snow Ground Reflectance and Snow Ground Reflectance for Daylighting.

## 1.7.24 Site:WaterMainsTemperature

The Site:WaterMainsTemperature object is used to calculate water temperatures delivered by underground water main pipes. The mains temperatures are used as default, make-up water temperature inputs for several plant objects, including: **WaterUse:Equipment**, **WaterUse:Connections**, **WaterHeater:Mixed** and **WaterHeater:Stratified**. The mains temperatures are also used in the water systems objects to model the temperature of cold water supplies.

Water mains temperatures are a function of outdoor climate conditions and vary with time of year. A correlation has been formulated to predict water mains temperatures based on two weather inputs:

- average annual outdoor air temperature (dry-bulb)
- maximum difference in monthly average outdoor air temperatures

These values can be calculated from annual weather data using the auxillary program CalcSoilSurfTemp preprocessor. For more information on the water mains temperatures correlation, see the *EnergyPlus Engineering Document*.

Alternatively, the Site:WaterMainsTemperature object can read values from a schedule. This is useful for measured data or when water comes from a source other than buried pipes, e.g., a river or lake.

If there is no Site:WaterMainsTemperature object in the input file, a default constant value of 10 °C is assumed.

### 1.7.24.1 Inputs

#### 1.7.24.1.1 Field: Calculation Method

This field selects the calculation method and must have the keyword Schedule, Correlation or CorrelationFromWeatherFile. If calculation method is CorrelationFromWeatherFile, the two numeric input fields below are ignored. Instead, EnergyPlus calculates them from weather file.

#### 1.7.24.1.2 Field: Schedule Name

If the calculation method is Schedule, the water mains temperatures are read from the schedule referenced by this field. If the calculation method is Correlation or CorrelationFromWeatherFile, this field is ignored.

#### 1.7.24.1.3 Field: Annual Average Outdoor Air Temperature

If the calculation method is Correlation, this field is used in the calculation as the annual average outdoor air temperature (dry-bulb) [C]. If the calculation method is Schedule or CorrelationFromWeatherFile, this field is ignored.

#### 1.7.24.1.4 Field: Maximum Difference In Monthly Average Outdoor Air Temperatures

If the calculation method is Correlation, this field is used in the calculation as the maximum difference in monthly average outdoor air temperatures [ $\Delta C$ ]. If the calculation method is Schedule or CorrelationFromWeatherFile, this field is ignored.

```
Site:WaterMainsTemperature,
  Correlation,  !- Calculation Method {SCHEDULE | CORRELATION | CORRELATIONFROMWEATHERFILE}
  ,           !- Schedule Name
  9.69,       !- Annual Average Outdoor Air Temperature {C}
  28.1;       !- Maximum Difference In Monthly Average Outdoor Air Temperatures {deltaC}
```

### 1.7.25 Site:Precipitation

The Site:Precipitation object is used to describe the amount of water precipitation at the building site over the course of the simulation run period. Precipitation includes both rain and the equivalent water content of snow. Precipitation is not yet described well enough in the many building weather data files. So this object can be used to provide the data using Schedule objects that define rates of precipitation in meters per hour. In 22.1 and later versions, Site::Precipitation is also used to set the rain indicator. During a weather file simulation (RunPeriod), if Use Weather File Rain Indicators is Yes and the precipitation rate is no less than 0.8 mm per hour, then the rain flag

is set to true. During a sizing simulation, the rain indicator defined in SizingPeriod:DesignDay, SizingPeriod:WeatherFileDays, or SizingPeriod:WeatherFileConditionType will be used instead.

A set of schedules for site precipitation have been developed for USA weather locations and are provided with EnergyPlus in the data set called PrecipitationSchedulesUSA.idf. The user can develop schedules however they want. The schedules in the data set were developed using EnergyPlus' weather file (EPW) observations and the average monthly precipitation for the closest weather site provided by NOAA. EPW files for the USA that were based on TMY or TMY2 include weather observations for Light/Moderate/Heavy rainfall, however most international locations do not include these observations. The values were modeled by taking the middle of the ranges quoted in the EPW data dictionary. The assumed piecewise function is shown below.

$$\text{Amount (m/hour)} = \begin{cases} \text{Light} = 0.0125 \\ \text{Moderate} = 0.052 \\ \text{Heavy} = 0.1 \end{cases} \quad (1.10)$$

The values were inserted on hour by hour basis for the month based on the observations. Then each month was rescaled to meet the average precipitation for the month based on the 30-year average (1971-2000) provided by the NOAA/NCDC. Therefore, the flags in the EPW file match the precipitation schedules for the USA. Note that summing the average monthly precipitation values will not give you the average yearly precipitation. The resulting value may be lower or higher than the average yearly value.

Once the typical rainfall pattern and rates are scheduled, the Site:Precipitation object provides a method of shifting the total rainfall up or down for design purposes. Wetter or drier conditions can be modeled by changing the Design Annual Precipitation although the timing of precipitation throughout the year will not be changed.

### 1.7.25.1 Inputs

#### 1.7.25.1.1 Field: Precipitation Model Type

Choose rainfall modeling options. Only available option is ScheduleAndDesignLevel.

#### 1.7.25.1.2 Field: Design Level for Total Annual Precipitation

Magnitude of total precipitation for an annual period to be used in the model. Value selected by the user to correspond with the amount of precipitation expected or being assumed for design purposes. The units are in meters. This field works with the following two fields to allow easily shifting the amounts without having to generate new schedules.

#### 1.7.25.1.3 Field: Precipitation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of precipitation. The precipitation rate schedule is analogous to weather file data. However, weather files for building simulation do not currently contain adequate data for such calculations. Therefore, EnergyPlus schedules are used to enter the pattern of precipitation events. The values in this schedule are the average rate of precipitation in meters per hour. The integration of these values over an annual schedule should equal the nominal annual precipitation.

#### 1.7.25.1.4 Field: Average Total Annual Precipitation

Magnitude of annual precipitation associated with the rate schedule. This value is used to normalize the precipitation.

IDF example:

```
Site:Precipitation,
  ScheduledAndDesignLevel, !- Precipitation Model Type
  0.75,                      !- Design Level Total Annual Precipitation {m/yr}
  PrecipitationSchd,          !- Schedule Name for Precipitation Rates
  0.80771;                   !- Average Total Annual Precipitation {m/yr}
```

---

## 1.7.26 RoofIrrigation

The RoofIrrigation object is used to describe the amount of irrigation on the ecoroof surface over the course of the simulation runperiod. This object is used to provide irrigation data using Schedule objects that define rates of irrigation in meters per hour. These schedules can be one of two types: Schedule, or SmartSchedule. Up till version 9.6, the schedule objects are necessary to describe the rates of roof irrigation. For newer versions, if the schedule is not defined, precipitation depth in the weather input .epw will be used instead. When rainfall data in the weather file is used, a warning message will be displayed. Please make sure the precipitation in the .epw is accurate. This <https://www.ncdc.noaa.gov/extremes/scec/records/all/maxp> could be a reference for sanity check of extreme values in the precipitation data. The tabular report “Monthly Precipitation Summary” provides a monthly summary of rainfall in the weather file and the amount used in the roof irrigation.

### 1.7.26.1 Inputs

#### 1.7.26.1.1 Field: Irrigation Model Type

Choose irrigation modeling options. Available options are **Schedule** and **SmartSchedule**. The **Schedule** type is used to force an irrigation schedule regardless of the current moisture state of the soil. The **SmartSchedule** type allows the precipitation schedule to be overridden if the current moisture state of the soil is greater than 40% saturated.

#### 1.7.26.1.2 Field: Irrigation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of irrigation. The values in this schedule are the average rate of irrigation in meters per hour.

#### 1.7.26.1.3 Field: Irrigation Maximum Saturation Threshold

Used with the SmartSchedule option in the Irrigation Model Type field to override the default 40% saturation limit for turning off the irrigation: values of 0 to 100 (percent) can be entered with 40% being the default.

IDF example:

```
RoofIrrigation,
  Schedule,      !- Irrigation Model Type
  IrrigationSchd; !- Schedule Name for Irrigation Rates
```

---

## 1.7.27 Solar and Visible Spectrum Objects

The next two objects enable users to enter solar and visible spectrum which is used to calculate the thermal and visual performance of windows if their glazings are defined with full spectral data. EnergyPlus versions 8.0 and older hard-wired the solar and visible spectrum. The solar spectrum assumes air mass 1.5 terrestrial solar global spectral irradiance values (W/m<sup>2</sup>-micron) on a 37° tilted surface, based on ISO 9845-1 and ASTM E 892; derived from Optics5 data file ISO-9845GlobalNorm.std, 10-14-99. The visible/photopic spectrum is based on CIE 1931 observer; ISO/CIE 10527, CIE Standard Calorimetric Observers; derived from Optics5 data file “CIE 1931 Color Match from E308.txt”, which is the same as WINDOW4 file Cie31t.dat.

## 1.7.28 Site:SolarAndVisibleSpectrum

The SolarAndVisibleSpectrum object is used to specify the solar and visible spectrum data which is used as spectral weighting function to calculate the window performance (transmittance and absorptance) in EnergyPlus. This is a unique object, if it is missing from an IDF file, the default (same as EnergyPlus version 8.0) solar and visible spectrum data will be used.

### 1.7.28.1 Inputs

#### 1.7.28.1.1 Field: Name

This field specifies the name of the SolarAndVisibleSpectrum object.

#### 1.7.28.1.2 Field: Spectrum Data Method

This field specifies the method used to enter the spectrum data. Two choices are available: Default and UserDefined. The choice Default will continue to use the hard-wired spectrum data in EnergyPlus (for backward compatibility). The choice UserDefined allows users to specify custom solar and visible spectrum data. The default choice is Default.

#### 1.7.28.1.3 Field: Solar Spectrum Data Name

This field is required if the Spectrum Data Method is set to UserDefined. This field references a spectrum dataset for solar.

#### 1.7.28.1.4 Field: Visible Spectrum Data Name

This field is required if the Spectrum Data Method is set to UserDefined. This field references a spectrum dataset for visible.

IDF example:

```
Site:SolarAndVisibleSpectrum,
  LocalSpectrum,           !- Name
  UserDefined,             !- Spectrum Data Method: Default, UserDefined
  SolarSpectrum,           !- Solar Spectrum Data Object Name
  VisibleSpectrum;         !- Visible Spectrum Data Object
```

## 1.7.29 Site:SpectrumData

The Site:SpectrumData object holds the user defined solar or visible spectrum data. For solar spectrum, up to 107 pairs of (wavelength, spectrum) can be entered. For visible spectrum, up to 81 pairs can be entered.

### 1.7.29.1 Inputs

#### 1.7.29.1.1 Field: Name

This field specifies the name of the SpectrumData object. The name must be unique across all SpectrumData objects.

#### 1.7.29.1.2 Field: Spectrum Data Type

This field specifies the type of spectrum data. Choices are Solar and Visible.

#### 1.7.29.1.3 Field: Wavelength <n>

This field specifies the n<sup>th</sup> wavelength in micron.

#### 1.7.29.1.4 Field: Spectrum <n>

This field specifies the n<sup>th</sup> spectrum corresponding to the nth wavelength.

IDF example:

```
Site:SpectrumData,
  SolarSpectrum, !- Name
  Solar,           !- Spectrum Data Type
  0.3,0,          !- up to 107 pair of (wavelength, spectrum)
  0.305,3.4,
  0.31,15.6,
  0.315,41.1,
  0.32,71.2,
  0.325,100.2,
  0.33,152.4,
  0.335,155.6,
  0.34,179.4,
  0.345,186.7,
  0.35,212,
  0.36,240.5,
  0.37,324,
  0.38,362.4,
  ...;
```

## 1.7.30 Climate Group Outputs

Climate related variables appear in two places for EnergyPlus outputs. Certain objects that are invariant throughout a simulation period have lines appear in the eplusout.eio file. For descriptions of this reporting, please see the Output Details and Examples document.

## 1.7.31 Weather Data Related Outputs

Variables related to ambient environment data are available at timestep and higher resolutions. Below is a variable dictionary of these variables and subsequent definitions:

- Zone,Average,Site Outdoor Air Drybulb Temperature [C]
- Zone,Average,Site Outdoor Air Dewpoint Temperature [C]
- Zone,Average,Site Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Site Outdoor Air Humidity Ratio [kgWater/kgAir]

- Zone,Average,Site Outdoor Air Relative Humidity [%]
- Zone,Average,Site Outdoor Air Barometric Pressure [Pa]
- Zone,Average,Site Wind Speed [m/s]
- Zone,Average,Site Wind Direction [deg]
- Zone,Average,Site Sky Temperature [C]
- Zone,Average,Site Horizontal Infrared Radiation Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Site Diffuse Solar Radiation Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Site Direct Solar Radiation Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Site Total Sky Cover []
- Zone,Average,Site Opaque Sky Cover []
- Zone,Sum,Site Precipitation Depth [m]
- Zone,Average,Site Ground Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Site Ground Temperature [C]
- Zone,Average,Site Surface Ground Temperature [C]
- Zone,Average,Site Deep Ground Temperature [C]
- Zone,Average,Site Simple Factor Model Ground Temperature [C]
- Zone,Average,Site Outdoor Air Enthalpy [J/kg]
- Zone,Average,Site Outdoor Air Density [kg/m<sup>3</sup>]
- Zone,Average,Site Solar Azimuth Angle [deg]
- Zone,Average,Site Solar Altitude Angle [deg]
- Zone,Average,Site Solar Hour Angle [deg]
- Zone,Average,Site Rain Status []
- Zone,Average,Site Snow on Ground Status []
- Zone,Average,Site Exterior Horizontal Sky Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Beam Illuminance [lux]
- Zone,Average,Site Exterior Beam Normal Illuminance [lux]
- Zone,Average,Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Beam Solar Radiation Luminous Efficacy [lum/W]

- Zone,Average,Site Daylighting Model Sky Clearness []
- Zone,Average,Sky Brightness for Daylighting Calculation []
- Zone,Average,Site Daylight Saving Time Status []
- Zone,Average,Site Day Type Index []
- Zone,Average,Site Mains Water Temperature [C]
- HVAC,Average,Site Precipitation Rate [m/s]
- HVAC,Sum,Site Precipitation Depth [m]
- HVAC,Sum,Water System Roof Irrigation Scheduled Depth[m]
- HVAC,Sum,Water System Roof Irrigation Actual Depth[m]

Note that these data values may be interpolated from “hour” points (ref: Weather Data Hourly Interpolation). Most of the data values represent the “average” over the reporting resolution period.

#### **1.7.31.1 Site Outdoor Air Drybulb Temperature [C]**

This is the outdoor dry-bulb temperature in degrees C.

#### **1.7.31.2 Site Outdoor Air Dewpoint Temperature [C]**

This is the outdoor dewpoint temperature in degrees C.

#### **1.7.31.3 Site Outdoor Air Wetbulb Temperature [C]**

The outdoor wet-bulb temperature is derived (at the timestep) from the values for dry-bulb temperature, humidity ratio and barometric pressure.

#### **1.7.31.4 Site Outdoor Air Humidity Ratio [kgWater/kgAir]**

The outdoor humidity ratio is derived (at the timestep) from the dry-bulb temperature, relative humidity and barometric pressure.

#### **1.7.31.5 Site Outdoor Air Relative Humidity [%]**

This is the outdoor relative humidity expressed in percent.

#### **1.7.31.6 Site Outdoor Air Barometric Pressure [Pa]**

This is the atmospheric/barometric pressure in Pa.

#### **1.7.31.7 Site Wind Speed [m/s]**

This is the outdoor wind speed in m/s.

### 1.7.31.8 Site Wind Direction [deg]

This is the wind direction (N = 0, E = 90, S = 180, W = 270).

### 1.7.31.9 Site Sky Temperature [C]

The sky temperature is derived from horizontal infrared radiation intensity. It is expressed in degrees C. The default calculation is shown below but this value may be modified by the WeatherProperty:SkyTemperature object. Note that Sigma is the Stefan-Boltzmann constant in the following equation:

$$\text{Sky Temperature} = \left( \frac{\text{Horizontal IR}}{\text{Sigma}} \right)^{\frac{1}{4}} - 273.15_{\text{Conversion from Kelvin to Centigrade}} \quad (1.11)$$

### 1.7.31.10 Site Horizontal Infrared Radiation Rate per Area [W/m<sup>2</sup>]

The horizontal infrared radiation intensity is expressed in W/m<sup>2</sup> based, if missing from the weather file, on opaque sky cover, sky emissivity, temperature and other factors. The general calculation of Site Horizontal Infrared Radiation Rate per Area is discussed in both the Engineering Reference and the Auxiliary Programs document.

### 1.7.31.11 Site Diffuse Solar Radiation Rate per Area [W/m<sup>2</sup>]

Diffuse solar is the amount of solar radiation in W/m<sup>2</sup> received from the sky (excluding the solar disk) on a horizontal surface.

### 1.7.31.12 Site Direct Solar Radiation Rate per Area [W/m<sup>2</sup>]

Site Direct Solar Radiation Rate per Area is amount of solar radiation in W/m<sup>2</sup> received within a 5.7° field of view centered on the sun. This is also known as Beam Solar.

### 1.7.31.13 Site Total Sky Cover []

This is the total sky cover in tenths of sky. The value ranges from 0 (clear) to 10 (full cover).

### 1.7.31.14 Site Opaque Sky Cover []

This is the opaque sky cover in tenths of sky. The value ranges from 0 (clear) to 10 (full cover).

### 1.7.31.15 Site Precipitation Depth [m]

This is the amount of liquid precipitation (m). The source of this field may be the weather file or the Site:Precipitation object. The weather file values are in millimeters, but the report here is in meters. Two separate entities are displayed – from the weather file the key value is “Environment”; from the Site:Precipitation object the key value is Site:Precipitation.

If the weather file does not have a liquid precipitation field but does have the present weather fields, then a heuristic calculation is attempted for both flagging when it is raining and the amount of precipitation. If the weather file does have liquid precipitation fields, then the output (e.g. monthly) can be compared with the weather file stat file.

### 1.7.31.16 Site Ground Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]

The ground reflected solar amount (W/m<sup>2</sup>) is derived from the Beam Solar, Diffuse Solar, User specified Ground Reflectance (for month) and Solar Altitude Angle:

Groundreflectedsolar

$$= (\text{Beamsolar} \cdot \cos(\text{SolarAltitudeAngle}) + \text{Diffusesolar}) \cdot \text{Groundreflectance}_{\text{month}} \quad (1.12)$$

where if the calculation returns a value < 0.0, then 0.0 will be reported.

### 1.7.31.17 Site Ground Temperature [C]

The ground temperature is reported in degrees C – this is a user-specified input by month.

### 1.7.31.18 Site Surface Ground Temperature [C]

The ground temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:Shallow) by month.

### 1.7.31.19 Site Deep Ground Temperature [C]

The ground temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:Deep) by month.

### 1.7.31.20 Site Simple Factor Model Ground Temperature [C]

The Site Simple Factor Model Ground Temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:FCfactorMethod) by month or gleaned from the weather file as noted in the description of the object.

### 1.7.31.21 Site Outdoor Air Enthalpy [J/kg]

Outdoor enthalpy is derived at each timestep from the Site Outdoor Air Drybulb Temperature and the Site Outdoor Air Humidity Ratio. It is reported in J/kg.

### 1.7.31.22 Site Outdoor Air Density [kg/m<sup>3</sup>]

Outdoor air density is derived at each timestep from the Site Outdoor Air Barometric Pressure, the Outdoor Dry-bulb temperature and the Outdoor Humidity Ratio. It is reported in units kg/m<sup>3</sup>.

### 1.7.31.23 Site Solar Azimuth Angle [deg]

The Solar Azimuth Angle (f) is measured from the North (clockwise) and is expressed in degrees. This is shown more clearly in the following figure.

### 1.7.31.24 Site Solar Altitude Angle [deg]

The Solar Altitude Angle (b) is the angle of the sun above the horizontal (degrees).

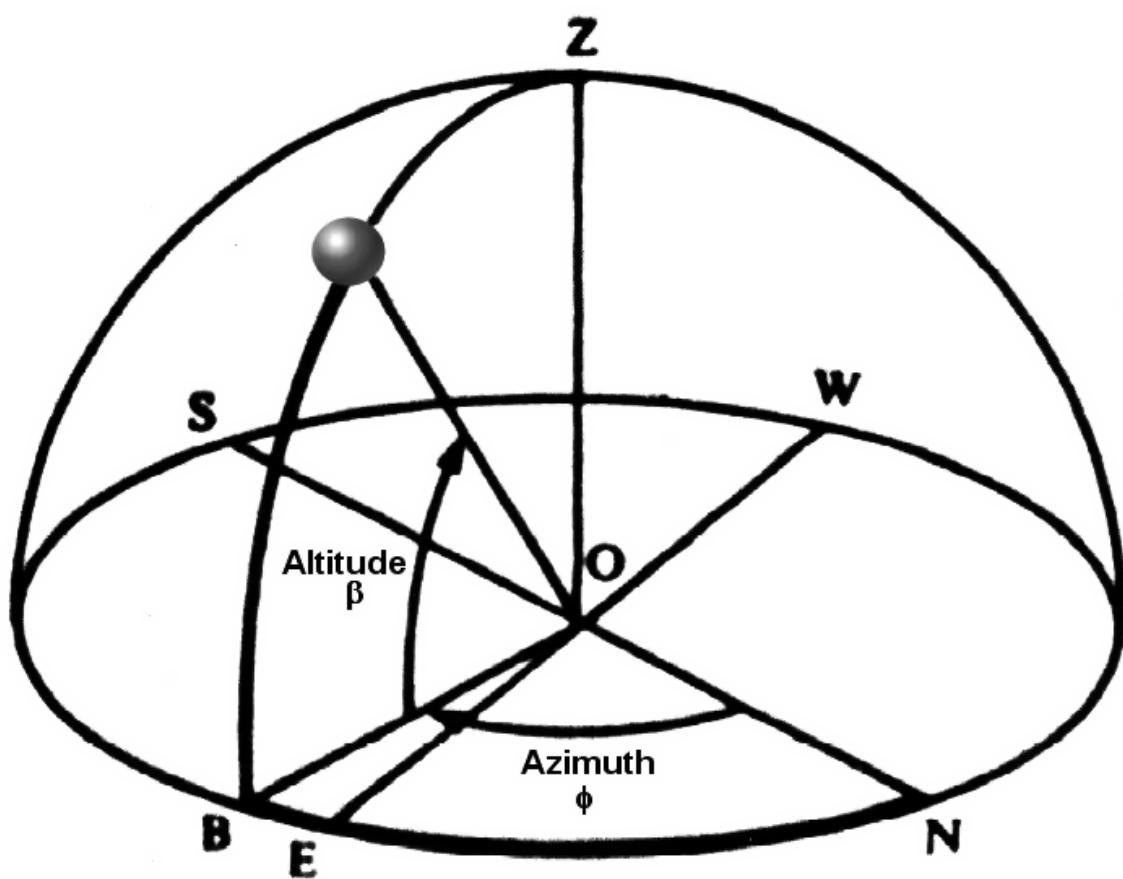

Figure 1.10: Solar Position Illustration

### 1.7.31.25 Site Solar Hour Angle [deg]

The Solar Hour Angle ( $H$ ) gives the apparent solar time for the current time period (degrees). It is common astronomical practice to express the hour angle in hours, minutes and seconds of time rather than in degrees. You can convert the hour angle displayed from EnergyPlus to time by dividing by 15. (Note that 1 hour is equivalent to 15 degrees;  $360^\circ$  of the Earth's rotation takes place every 24 hours.) The relationship of angles in degrees to time is shown in the following table:

Table 1.12: Relationship of Angles (degrees) to Time

Unit of Angle	Equivalent time
1 radian	3.819719 hours
1 degree	4 minutes
1 arcmin	4 seconds
1 arcsec	0.066667 seconds

### 1.7.31.26 Site Rain Status []

This field shows whether or not (1 = yes, 0 = no) the weather shows “raining”. For a Design Day, one can denote rain for the entire day but not timestep by timestep. Weather files may indicate rain for a single time interval. This is an “averaged” field – thus a 1 shown for a time period (e.g. daily reporting) means that it was raining during each timestep of that period.

### 1.7.31.27 Site Snow on Ground Status []

This field shows whether or not (1 = yes, 0 = no) the weather shows “snow on the ground”. For a Design Day, one can denote snow for the entire day but not timestep by timestep. Weather files may indicate snow (snow depth) for a single time interval. This is an “averaged” field – thus a 1 shown for a time period (e.g. daily reporting) means that there was snow on the ground during each timestep of that period.

### 1.7.31.28 Site Daylight Saving Time Status []

This field shows when daylight saving time (1 = yes, 0 = no) is in effect. Though shown as an average variable, this value is only set on a daily basis.

### 1.7.31.29 Site Day Type Index []

This field shows what “day type” the current day is. Day types are (1 = Sunday, 2 = Monday, etc.) with Holiday = 8, SummerDesignDay = 9, WinterDesignDay = 10, CustomDay1 = 11, CustomDay2 = 12. Though shown as an average variable, this value is only set on a daily basis.

### 1.7.31.30 Site Mains Water Temperature [C]

The value of the Water Mains Temperature is reported in C following the calculation shown in the Water Mains Temperature object.

**1.7.31.31 Site Precipitation Rate [m/s]****1.7.31.32 Site Precipitation Depth [m]**

The rate and quantity of precipitation at the site. These outputs are only available if a Site Precipitation object is used. Precipitation is measured in meters.

**1.7.31.33 Water System Roof Irrigation Scheduled Depth[m]**

This is the scheduled amount of irrigation for the green roof (ecoroof) based on the user input. Amount is measured in meters.

**1.7.31.34 Water System Roof Irrigation Actual Depth[m]**

This is the actual amount of irrigation for the green roof (ecoroof) based on the scheduled user input and moisture state/saturation of the soil. Amount is measured in meters.

**1.7.32 Outputs for local temperature/wind speed calculations**

Local atmospheric properties for outdoor air temperature and wind speed are separately calculated and reported for all zones, surfaces, and outdoor air nodes. The output variables are associated with their respective objects:

- Zone,Average,Zone Outdoor Air Drybulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wind Speed [m/s]
- Zone,Average,Surface Ext Outdoor Dry Bulb [C]
- Zone,Average,Surface Ext Outdoor Wet Bulb [C]
- Zone,Average,Surface Ext Wind Speed [m/s]
- HVAC,Average,System Node Temperature [C] (for OUTDOOR AIR NODE object)

**1.7.32.1 Zone Outdoor Air Drybulb Temperature [C]**

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

**1.7.32.2 Zone Outdoor Air Wetbulb Temperature [C]**

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

**1.7.32.3 Zone Outdoor Air Wind Speed [m/s]**

The outdoor wind speed calculated at the height above ground of the zone centroid.

#### 1.7.32.4 Surface Ext Outdoor Dry Bulb [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid.

#### 1.7.32.5 Surface Ext Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid.

#### 1.7.32.6 Surface Ext Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid.

#### 1.7.32.7 System Node Temperature [C]

When reporting for the **OutdoorAir:Node** object, this is the outdoor air dry-bulb temperature calculated at the height above ground of the node, if height is specified in the input.

## 1.8 Group – Schedules

This group of objects allows the user to influence scheduling of many items (such as occupancy density, lighting, thermostatic controls, occupancy activity). In addition, schedules are used to control shading element density on the building.

EnergyPlus schedules consist of three pieces: a day description, a week description, and an annual description. An optional element is the schedule type. Each description level builds off the previous sub-level. The day description is simply a name and the values that span the 24 hours in a day to be associated with that name. The week description also has an identifier (name) and twelve additional names corresponding to previously defined day descriptions. There are names for each individual day of the week plus holiday, summer design day, winter design day and two more custom day designations. Finally, the annual schedule contains an identifier and the names and FROM-THROUGH dates of the week schedules associate with this annual schedule. The annual schedule can have several FROM-THROUGH date pairs. One type of schedule reads the values from an external file to facilitate the incorporation of monitored data or factors that change throughout the year.

Schedules are processed by the EnergyPlus Schedule Manager, stored within the Schedule Manager and are accessed through module routines to get the basic values (timestep, hourly, etc). Values are resolved at the Zone Timestep frequency and carry through any HVAC timesteps.

### 1.8.1 Day Type

A brief description of “Day Type” which is used in the SizingPeriod objects, RunPeriodControl:SpecialDays object, the Sizing objects and also used by reference in the **Schedule:Week:Daily** object (discussed later in this section).

Schedules work on days of the week as well as certain specially designated days. Days of the week are the normal – Sunday, Monday, Tuesday, Wednesday, Thursday, Friday and Saturday. Special day types that can be designated are: Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2. These day types can be used at the user’s convenience to designate special scheduling (e.g. lights, electric equipment, set point temperatures) using these days as reference.

For example, a normal office building may have normal “occupancy” rules during the weekdays but significantly different use on weekend. For this, you would set up rules/schedules based on the weekdays (Monday through Friday, in the US) and different rules/schedules for the weekend (Saturday and Sunday, in the US). However, you could also specially designate SummerDesignDay and WinterDesignDay schedules for sizing calculations. These schedules can be activated by setting the Day Type field in the Design Day object to the appropriate season (**SummerDesignDay** for cooling design calculations; **WinterDesignDay** for heating design calculations).

In a different building, such as a theater/playhouse, the building may only have occupancy during certain weeks of the year and/or certain hours of certain days. If it was every week, you could designate the appropriate values during the “regular” days (Sunday through Saturday). But this would also be an ideal application for the “CustomDay1” and/or “CustomDay2”. Here you would set the significant occupancy, lighting, and other schedules for the custom days and use unoccupied values for the normal weekdays. Then, using a weather file and setting special day periods as appropriate, you will get the “picture” of the building usage during the appropriate periods.

## 1.8.2 ScheduleTypeLimits

Schedule types can be used to validate portions of the other schedules. Hourly day schedules, for example, are validated by range – minimum/maximum (if entered) – as well as numeric type (continuous or discrete). Annual schedules, on the other hand, are only validated for range – as the numeric type validation has already been done.

### 1.8.2.1 Inputs

#### 1.8.2.1.1 Field: Name

This alpha field should contain a unique (within the schedule types) designator. It is referenced wherever Schedule Type Limits Names can be referenced.

#### 1.8.2.1.2 Field: Lower Limit Value

In this field, the lower (minimum) limit value for the schedule type should be entered. If this field is left blank, then the schedule type is not limited to a minimum/maximum value range.

#### 1.8.2.1.3 Field: Upper Limit Value

In this field, the upper (maximum) limit value for the schedule type should be entered. If this field is left blank, then the schedule type is not limited to a minimum/maximum value range.

#### 1.8.2.1.4 Field: Numeric Type

This field designates how the range values are validated. Using **Continuous** in this field allows for all numbers, including fractional amounts, within the range to be valid. Using **Discrete** in this field allows only integer values between the minimum and maximum range values to be valid.

#### 1.8.2.1.5 Field: Unit Type

This field is used to indicate the kind of units that may be associated with the schedule that references the ScheduleTypeLimits object. It is used by IDF Editor to display the appropriate SI

and IP units. This field is not used by EnergyPlus. The available options are shown below. If none of these options are appropriate, select **Dimensionless**.

- Dimensionless
- Temperature
- DeltaTemperature
- PrecipitationRate
- Angle
- Convection Coefficient
- Activity Level
- Velocity
- Capacity
- Power
- Availability
- Percent
- Control
- Mode

Several IDF Examples will illustrate the use:

```
ScheduleTypeLimits,Any Number; ! Not limited
ScheduleTypeLimits,Fraction, 0.0 , 1.0 ,CONTINUOUS;
ScheduleTypeLimits,Temperature,-60,200,CONTINUOUS;
ScheduleTypeLimits,Control Type,0,4,DISCRETE;
ScheduleTypeLimits,On/Off,0,1,DISCRETE;
```

---

### 1.8.3 Day Schedules

The day schedules perform the assignment of pieces of information across a 24 hour day. This can occur in various fashions including a 1-per hour assignment, a user specified interval scheme or a list of values that represent an hour or portion of an hour.

### 1.8.4 Schedule:Day:Hourly

The Schedule:Day:Hourly contains an hour-by-hour profile for a single simulation day.

#### 1.8.4.1 Inputs

##### 1.8.4.1.1 Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

#### 1.8.4.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see [ScheduleTypeLimits](#) object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.8.4.1.3 Field: Hour Values (1-24)

These fields contain the hourly values for each of the 24 hours in a day. (Hour field 1 represents clock time 00:00:01 AM to 1:00:00 AM, hour field 2 is 1:00:01 AM to 2:00:00 AM, etc.) The values in these fields will be passed to the simulation as indicated for “scheduled” items.

An IDF example:

```
Schedule:Day:Hourly, Day On Peak, Fraction,
0.,0.,0.,0.,0.,0.,1.,1.,1.,1.,1.,1.,1.,0.,0.,0.,0.,0.,0.;
```

### 1.8.5 Schedule:Day:Interval

The Schedule:Day:Interval introduces a slightly different way of entering the schedule values for a day. Using the intervals, you can shorten the “hourly” input of the “[Schedule:Day:Hourly](#)” object to 2 fields. And, more importantly, you can enter an interval that represents only a portion of an hour. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

#### 1.8.5.1 Inputs

##### 1.8.5.1.1 Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

##### 1.8.5.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see [ScheduleTypeLimits](#) object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

##### 1.8.5.1.3 Field: Interpolate to Timestep

Three possible inputs are available for this field: Average, Linear, and No. The default value is No.

If “Average” is entered, it is used to apply values that aren’t coincident with the given timestep (ref: Timestep) intervals. If “Average” is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. For example, if “Average” is entered and the interval is every 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. In earlier versions of EnergyPlus, this was the Yes option for the field.

If “No” is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value. For the same input entries but “no” for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5. No is the default for this field.

If “Linear” is entered, then the value that is used is based on the linear interpolation between successive values. With linear, if the value at 1:00 is 0.0 and the value at 2:00 is 10.0, with fifteen minute timesteps, the value at 1:15 would be 2.5, the value at 1:30 would be 5.0 and the value at 1:45 would be 7.5.

#### 1.8.5.1.4 Field-Set: Time and Value (extensible object)

To specify each interval, both an “until” time (which includes the designated time) and the value must be given. This object is extensible, so additional pairs of the following two fields can be added to the end of this object.

#### 1.8.5.1.5 Field: Time

The value of each field should represent clock time (standard) in the format “Until: HH:MM”. 24 hour clock format (i.e. 1PM is 13:00) is used. Note that Until: 7:00 includes all times up through 07:00 or 7am.

#### 1.8.5.1.6 Field: Value

This represents the actual value to be passed to the simulation at the appropriate timestep. (Using interpolation value as shown above). Limits on the values are indicated by the Schedule Type Limits Name field of this object.

And an example of use:

```
Schedule:Day:Interval,
  dd winter rel humidity, !- Name
  Percent,           !- Schedule Type Limits Name
  No,                !- Interpolate to Timestep
  until: 24:00,      !- Time 1
  74;               !- Value Until Time 1
```

### 1.8.6 Schedule:Day>List

To facilitate possible matches to externally generated data intervals, this object has been included. In similar fashion to the [Schedule:Day:Interval](#) object, this object can also include “sub-hourly” values but must represent a complete day in its list of values.

#### 1.8.6.1 Inputs

##### 1.8.6.1.1 Field: Name

This field should contain a unique (within all day schedules) designation for this schedule. It is referenced by week schedules to define the appropriate schedule values.

##### 1.8.6.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see [ScheduleTypeLimits](#) object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

### 1.8.6.1.3 Field: Interpolate to Timestep

Three possible inputs are available for this field: Average, Linear, and No. The default value is No.

If “Average” is entered, it is used to apply values that aren’t coincident with the given timestep (ref: Timestep) intervals. If “Average” is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. For example, if “Average” is entered and the interval is every 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. In earlier versions of EnergyPlus, this was the Yes option for the field.

If “No” is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value. For the same input entries but “no” for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5. No is the default for this field.

If “Linear” is entered, then the value that is used is based on the linear interpolation between successive values. With linear, if the value at 1:00 is 0.0 and the value at 2:00 is 10.0, with fifteen minute timesteps, the value at 1:15 would be 2.5, the value at 1:30 would be 5.0 and the value at 1:45 would be 7.5.

### 1.8.6.1.4 Field: Minutes Per Item

This field allows the “list” interval to be specified in the number of minutes for each item. The value here must be  $\leq 60$  and evenly divisible into 60 (same as the timestep limits).

### 1.8.6.1.5 Field Value 1 (same definition for each value – up to 1440 (24\*60) allowed)

This is the value to be used for the specified number of minutes.

For example:

```
Schedule:Day>List,
Myschedule, ! name
Fraction,   ! Schedule type
No,          ! Interpolate value
30,          ! Minutes per item
0.0,         ! from 00:01 to 00:30
0.5,         ! from 00:31 to 01:00
<snipped>
```

## 1.8.7 Week Schedule(s)

The week schedule object(s) perform the task of assigning the day schedule to day types in the simulation. The basic week schedule is shown next.

## 1.8.8 Schedule:Week:Daily

### 1.8.8.1 Inputs

#### 1.8.8.1.1 Field: Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule values.

### 1.8.8.1.2 Field: Schedule Day Name Fields (12 day types – Sunday, Monday, ... )

These fields contain day schedule names for the appropriate day types. Days of the week (or special days as described earlier) will then use the indicated hourly profile as the actual schedule value.

An IDF example:

```
Schedule:Week:Daily, Week on Peak,
Day On Peak,Day On Peak,Day On Peak;
```

---

## 1.8.9 Schedule:Week:Compact

Further flexibility can be realized by using the Schedule:Week:Compact object. In this the fields, after the name is given, a “for” field is given for the days to be assigned and then a dayschedule name is used.

### 1.8.9.1 Inputs

#### 1.8.9.1.1 Field:Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule values.

#### 1.8.9.1.2 Field-Set – DayType List#, Schedule:Day Name #

Each assignment is made in a pair-wise fashion. First the “days” assignment and then the dayschedule name to be assigned. The entire set of day types must be assigned or an error will result.

#### 1.8.9.1.3 Field: DayType List #

This field can optionally contain the prefix “For” for clarity. Multiple choices may then be combined on the line. Choices are: Weekdays, Weekends, Holidays, Alldays, SummerDesignDay, WinterDesignDay, Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, CustomDay1, CustomDay2. In fields after the first “for”, AllOtherDays may also be used. Note that the colon (:) after the For is optional but is suggested for readability.

#### 1.8.9.1.4 Field: Schedule:Day Name #

This field contains the name of the day schedule (any of the Schedule:Day object names) that is to be applied for the days referenced in the prior field.

Some IDF examples:

```
Schedule:Week:Compact, Week on Peak,
For: AllDays,
Day On Peak;
```

```
Schedule:Week:Compact, WeekDays on Peak,
WeekDays,
Day On Peak,
AllOtherDays
Day Off Peak;
```

---

## 1.8.10 Schedule:Year

The yearly schedule is used to cover the entire year using references to week schedules (which in turn reference day schedules). If the entered schedule does not cover the entire year, a fatal error will result.

### 1.8.10.1 Inputs

#### 1.8.10.1.1 Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various “scheduled” items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

#### 1.8.10.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.8.10.1.3 Field Set (WeekSchedule, Start Month and Day, End Month and Day)

Each of the designated fields is used to fully define the schedule values for the indicated time period. Up to 53 sets can be used. An error will be noted and EnergyPlus will be terminated if an incomplete set is entered. Missing time periods will also be noted as warning errors; for these time periods a zero (0.0) value will be returned when a schedule value is requested. Each of the sets has the following 5 fields:

#### 1.8.10.1.4 Field: Schedule Week Name #

This field contains the appropriate WeekSchedule name for the designated time period.

#### 1.8.10.1.5 Field: Start Month #

This numeric field is the starting month for the schedule time period.

#### 1.8.10.1.6 Field: Start Day #

This numeric field is the starting day for the schedule time period.

#### 1.8.10.1.7 Field: End Month #

This numeric field is the ending month for the schedule time period.

#### 1.8.10.1.8 Field: End Day #

This numeric field is the ending day for the schedule time period.

Note that there are many possible periods to be described. An IDF example with a single period:

```
Schedule:Year, On Peak, Fraction,  
  Week On Peak, 1,1, 12,31;
```

And a multiple period illustration:

```
Schedule:Year,CoolingCoilAvailSched,Fraction,
FanAndCoilAllOffWeekSched, 1,1, 3,31,
FanAndCoilSummerWeekSched, 4,1, 9,30,
FanAndCoilAllOffWeekSched, 10,1, 12,31;
```

The following definition will generate an error (if any scheduled items are used in the simulation):

```
Schedule:Year,MySchedule,Fraction,4,1,9,30;
```

## 1.8.11 Schedule:Compact

For flexibility, a schedule can be entered in “one fell swoop”. Using the Schedule:Compact object, all the features of the schedule components are accessed in a single command. Like the “regular” schedule object, each schedule:compact entry must cover all the days for a year. Additionally, the validations for DaySchedule (i.e. must have values for all 24 hours) and WeekSchedule (i.e. must have values for all day types) will apply. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

This object is an unusual object for description. For the data the number of fields and position are not set, they cannot really be described in the usual Field # manner. Thus, the following description will list the fields and order in which they must be used in the object. The name and schedule type are the exceptions:

### 1.8.11.1 Inputs

#### 1.8.11.1.1 Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various “scheduled” items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

#### 1.8.11.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.8.11.1.3 Field-Set (Through, For, Interpolate, Until, Value)

Each compact schedule must contain the elements Through (date), For (days), Interpolate (optional), Until (time of day) and Value. In general, each of the “titled” fields must include the “title”. Note that the colon (:) after these elements (Through, For, Until) is optional but is suggested for readability.

#### 1.8.11.1.4 Field: Through

This field starts with “Through:” and contains the ending date for the schedule period (may be more than one). Refer to Table 1.9. Date Field Interpretation for information on date entry – note that only Month-Day combinations are allowed for this field. Each “through” field generates a new WeekSchedule named “Schedule Name”\_wk\_# where # is the sequential number for this compact schedule.

#### 1.8.11.1.5 Field: For

This field starts with “For:” and contains the applicable days (reference the compact week schedule object above for complete description) for the 24 hour period that must be described. Each “for” field generates a new DaySchedule named “Schedule Name”\_dy\_# where # is the sequential number for this compact schedule.

#### 1.8.11.1.6 Field: Interpolate (optional)

This field, if used, starts with “Interpolate:” and contains the word “Average”, “Linear” or “No”. If this field is not used, it should not be blank – rather just have the following field appear in this slot.

If “Average” is entered, it is used to apply values that aren’t coincident with the given timestep (ref: Timestep) intervals. If “Average” is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. For example, if “Average” is entered and the interval is every 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. In earlier versions of EnergyPlus, this was the Yes option for the field.

If “No” is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value. For the same input entries but “no” for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5. No is the default for this field.

If “Linear” is entered, then the value that is used is based on the linear interpolation between successive values. With linear, if the value at 1:00 is 0.0 and the value at 2:00 is 10.0, with fifteen minute timesteps, the value at 1:15 would be 2.5, the value at 1:30 would be 5.0 and the value at 1:45 would be 7.5.

#### 1.8.11.1.7 Field: Until

This field contains the ending time (again, reference the interval day schedule discussion above) for the current days and day schedule being defined.

#### 1.8.11.1.8 Field: Value

Finally, the value field is the schedule value for the specified time interval.

And, some IDF examples:

```

Schedule:Compact,
POFF,          !- Name
Fraction,      !- Schedule Type Limits Name
Through: 4/30,
For: AllDays,
Until: 24:00, 1.0,
Through: 12/31,
For: Weekdays,
Until: 7:00,   .1,
Until: 17:00,  1.0,
Until: 24:00,  .1,
For: Weekends Holidays,
Until: 24:00,  .1,
For: AllOtherDays,
Until: 24:00,  .1;

! Schedule Continuous
Schedule:Compact,
Continuous,
on/off,
```

```

Through: 12/31,
For: AllDays,
Until: 24:00, 1.0;

! Schedule Daytime Ventilation
Schedule:Compact,
Daytime Ventilation,
Fraction,
Through: 12/31,
For: Weekdays SummerDesignDay,
Until: 08:00, 0.0,
Until: 18:00, 1.0,
Until: 24:00, 0.0,
For: Weekends WinterDesignDay,
Until: 10:00, 0.0,
Until: 16:00, 1.0,
Until: 24:00, 0.0,
For: Holidays AllOtherDays,
Until: 24:00, 0.0;

```

---

## 1.8.12 Schedule:Constant

The constant schedule is used to assign a constant hourly value. This schedule is created when a fixed hourly value is desired to represent a period of interest (e.g., always on operation mode for supply air fan).

### 1.8.12.1 Inputs

#### 1.8.12.1.1 Field: Name

This field should contain a unique name designation for this schedule. It is referenced by Schedules to define the appropriate schedule value.

#### 1.8.12.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see [ScheduleTypeLimits](#) object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.8.12.1.3 Field: Hourly Value

This field contains a constant real value. A fixed value is assigned as an hourly value.

An IDF example:

```

Schedule:Constant,
AlwaysOn,      !- Name
On/Off,        !- Schedule Type Limits Name
1.0;          !- Hourly Value

ScheduleTypeLimits,
On/Off,        !- Name
0,            !- Lower Limit Value
1,            !- Upper Limit Value
DISCRETE,     !- Numeric Type
Availability; !- Unit Type

```

---

### 1.8.13 Schedule:File

At times, data is available from a building being monitored or for factors that change throughout the year. The Schedule:File object allows this type of data to be used in EnergyPlus as a schedule. Schedule:File can also be used to read in hourly or sub-hourly schedules computed by other software or developed in a spreadsheet or other utility.

The format for the data file referenced is a text file with values separated by commas (or other optional delimiters) with one line per hour. The file may contain header lines that are skipped. The file should contain values for an entire year (8760 or 8784 hours of data) or a warning message will be issued. Multiple schedules may be created using a single external data file or multiple external data files may be used. The first row of data must be for January 1, hour 1 (or timestep 1 for subhourly files).

Schedule:File may be used along with the [FuelFactors](#) object and TDV files in the DataSets directory to compute Time Dependent Valuation based source energy as used by the California Energy Commission's Title 24 Energy Code. See Fuel Factor for more discussion on Time Dependent Valuation.

Two optional fields: **Interpolate to Timestep** and **Minutes per Item** allow for the input of sub-hourly schedules (similar to the [Schedule:Day>List](#) object).

#### 1.8.13.1 Inputs

##### 1.8.13.1.1 Field: Name

This field should contain a unique (between [Schedule:Year](#), [Schedule:Compact](#), and [Schedule:File](#)) designation for the schedule. It is referenced by various “scheduled” items (e.g. [Lights](#), [People](#), [Infiltration](#), [FuelFactors](#)) to define the appropriate schedule values.

##### 1.8.13.1.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see [ScheduleTypeLimits](#) object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

##### 1.8.13.1.3 Field: File Name

This field contains the name of the file that contains the data for the schedule. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

##### 1.8.13.1.4 Field: Column Number

The column that contains the value to be used in the schedule. The first column is column one. If no data for a row appears for a referenced column the value of zero is used for the schedule value for that hour.

### 1.8.13.1.5 Field: Rows to Skip at Top

Many times the data in a file contains rows (lines) that are describing the files or contain the names of each column. These rows need to be skipped and the number of skipped rows should be entered for this field. The next row after the skipped rows must contain data for January 1, hour 1.

### 1.8.13.1.6 Field: Number of Hours of Data

The value entered in this field should be either 8760 or 8784 as the number of hours of data. 8760 does not include the extra 24 hours for a leap year (if needed). 8784 will include the possibility of leap year data which can be processed according to leap year indicators in the weather file or specified elsewhere. Note if the simulation does not have a leap year specified but the schedule file contains 8784 hours of data, the first 8760 hours of data will be used. The schedule manager will not know to skip the 24 hours representing February 29.

### 1.8.13.1.7 Field: Column Separator

This field specifies the character used to separate columns of data if the file has more than one column. The choices are: Comma, Tab, Fixed (spaces fill each column to a fixed width), or Semicolon. The default is Comma.

### 1.8.13.1.8 Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren't coincident with the given timestep (ref: TimeStep object) intervals. If "Yes" is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If "No" is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if "yes" is entered and the minutes per item is 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but "no" for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

### 1.8.13.1.9 Field: Minutes Per Item

This field represents the number of minutes for each item – in this case each line of the file. The value here must be  $\leq 60$  and evenly divisible into 60 (same as the timestep limits).

Here is an IDF example:

```
Schedule:File,
electTDVfromCZ0ires, !- Name
Any Number,           !- ScheduleType
TDV_kBtu_C TZ01.csv, !- Name of File
2,                  !- Column Number
4,                  !- Rows to Skip at Top
8760,               !- Number of Hours of Data
Comma;              !- Column Separator
```

or with a relational path:

```
Schedule:File,
electTDVfromCZ0ires, !- Name
Any Number,           !- ScheduleType
DataSets\TDV\TDV_kBtu_C TZ01.csv, !- Name of File
2,                  !- Column Number
4;                  !- Rows to Skip at Top
```

A sub-hourly indication. Note that this is identical to an hourly file because there are 60 minutes per item – the number of hours defaults to 8760 and the column separator defaults to a comma. If the number of minutes per item had been, say, 15, then the file would need to contain  $8760*4$  or 35,040 rows for this item.

```
Schedule:File,
elecTDVfromCZ06com, !- Name
Any Number,          !- Schedule Type Limits Name
DataSets\TDV\TDV_2008_kBtu_CTZ06.csv, !- File Name
1,                  !- Column Number
4,                  !- Rows to Skip at Top
,                  !- Number of Hours of Data
,                  !- Column Separator
,                  !- Interpolate to Timestep
60;                !- Minutes per Item
```

### 1.8.13.1.10 Field: Adjust Schedule for Daylight Savings

This field indicates whether or not to shift the schedule forward an hour during daylight savings time. If “Yes” the schedule skips forward an hour in the CSV on the “spring forward” day and repeats an hour on the “fall back” day. If “No”, the schedule is read and applied in standard time, without adjusting for daylight savings time (**RunPeriodControl:DaylightSavingTime**). This indicator is defaulted to “Yes” if no input is provided.

Here is an IDF example:

```
Schedule:File,
TestName,          !- Name
Any Number,        !- Schedule Type Limits Name
schedulefile.csv, !- File Name
2,                !- Column Number
1,                !- Rows to Skip at Top
8760,             !- Number of Hours of Data
Comma,            !- Column Separator
No,               !- Interpolate to Timestep
60,               !- Minutes per Item
No;               !- Adjust Schedule for Daylight Savings
```

### 1.8.13.2 Outputs

An optional report can be used to gain the values described in the previous Schedule objects. This is a condensed reporting that illustrates the full range of schedule values – in the style of input: DaySchedule, WeekSchedule, Annual Schedule.

```
! will give them on hourly increments (day schedule resolution)
Output:Schedules, Hourly;
! will give them at the timestep of the simulation
Output:Schedules, Timestep;
```

This report is placed on the eplusout.eio file. Details of this reporting are shown in the Output Details and Examples document.

#### 1.8.13.2.1 Schedule Value Output

```
Zone,Average,Schedule Value {}
```

### 1.8.13.2.2 Schedule Value

This is the schedule value (as given to whatever entity that uses it). It has no units in this context because values may be many different units (i.e. temperatures, fractions, watts). For best results, you may want to apply the schedule name when you use this output variable to avoid output proliferation. For example, the following reporting should yield the values shown above, depending on day of week and day type:

```
Output:Variable,People_Shopping_Sch,Schedule Value,hourly;
Output:Variable,Activity_Shopping_Sch,Schedule Value,hourly;
```

## 1.8.14 Schedule:File:Shading

The **Schedule:File:Shading** object allows shading schedules to be imported altogether from a file exported using **ShadowCalculation** Output External Shading Calculation Results. The object can also be used to read in hourly or sub-hourly schedules of the sunlit fraction of all exterior surfaces computed by other software or developed in a spreadsheet or other utility.

The format for the data file is Comma-separated values (CSV). The CSV file referenced is a text file with values separated by commas (or other optional delimiters) with one line per timestep. Each column stores the annual shading sunlit fraction schedule data of an exterior surface. The sunlit fraction is only overwritten and used when the sun is above horizon at a certain time step. To map to the surface, each column should name its column header exactly the same with the surface name defined in the **Surface:Detailed** object. If any surface name is missing, the sunlit fraction of this surface will be set to 1.0 during the run period, which means no shading will be assigned for this surface, and a warning message will be issued. The file should contain values for an entire year with the exact same number of rows as the total number of time steps in a year (number of days in a year \* number of hours per day \* number of time steps per hour). Time step should be consistent with the setting in the **Timestep** object. Otherwise, an error will be issued.

The first row of the CSV file should be the header, and the first column of the CSV file should be the timestamp and is not imported.

With a **Schedule:File:Shading** object defined, the shading schedules for all exterior surfaces (if defined) can be imported altogether without repeatedly defining **Schedule:File** objects.

### 1.8.14.1 Inputs

#### 1.8.14.1.1 Field: File Name

This field contains the name of the file that contains the data for the shading schedules. The field should include a full path with file name, for best results. The field must be  $\leq 100$  characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

Here is an IDF example:

```
Schedule:File,
  epluss shading.csv;    !- Name of File
```

## 1.9 Group – Surface Construction Elements

This group of objects describes the physical properties and configuration for the building envelope and interior elements. That is, the walls, roofs, floors, windows, doors for the building.

### 1.9.1 Specifying the Building Envelope

Building element constructions in EnergyPlus are built from the basic thermal and other material property parameters in physical constructions. Materials are specified by types and named. Constructions are defined by the composition of materials. Finally, surfaces are specified for the building with geometric coordinates as well as referenced constructions.

### 1.9.2 Material and Material Properties

There are several material “types” which may be used to describe layers within opaque construction elements. The choice of which of these types to use is left up to the user. However, some guidance as to which material type to use is appropriate before describing each in detail. The opaque types are:

- Material
- Material:NoMass
- Material:AirGap
- Material:RoofVegetation
- Material:InfraredTransparent

**Material** is the “preferred” type of material. This requires knowledge of many of the thermal properties of the material, but it allows EnergyPlus to take into account the thermal mass of the material and thus allows the evaluation of transient conduction effects. **Material:NoMass** is similar in nature but only requires the thermal resistance (R-value) rather than the thickness, thermal conductivity, density, and specific heat. Note that using a simple R-value only material forces EnergyPlus to assume steady state heat conduction through this material layer. Finally, **Material:AirGap** should only be used for an air gap between other layers in a construction. This type assumes that air is sufficiently lightweight to require only an R-value. In addition, since it is not exposed to any external environment, surface properties such as absorptance are not necessary. **Material:RoofVegetation** is used to help model “green roofs”. **Material:InfraredTransparent** is used similarly to the NoMass materials. Each of these materials is described in more detail below.

There are several material additions that can be made to the basic material properties. These additional material types are:

- MaterialProperty:MoisturePenetrationDepth:Settings
- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Diffusion

- MaterialProperty:HeatAndMoistureTransfer:Settings
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity
- MaterialProperty:PhaseChange
- MaterialProperty:PhaseChangeHysteresis

These material property objects are used in conjunction with the basic material specification and reference back to the name of the basic material type. Without the basic material type specified the program, will give a severe error and terminate. For example, specifying the moisture materials and changing the **HeatBalanceAlgorithm** to a moisture simulation will allow the moisture simulation to take place.

### 1.9.3 Material

This definition should be used when the four main thermal properties (thickness, conductivity, density, and specific heat) of the material are known. This syntax is used to describe opaque construction elements only.

When a Material is used for the Construction of a building surface, care should be taken to not attempt to model assemblies that were not included in the intended scope of applicability for the underlying heat transfer models. The building surface models are for normal applications to building energy efficiency where the main focus is on assemblies with some thermal resistance. Extremely thin and/or highly conductive material layers should be neglected from the Construction rather than included because they will not contribute to the assembly's overall thermal resistance or heat capacity. For some cases, thin and/or highly conductive materials are a serious problem for the heat transfer modeling and the values for thickness, conductivity, density and specific heat are checked for appropriateness. This check calculates the Material's thermal diffusivity from the inputs for conductivity, density, and specific heat and compares it to a maximum threshold of 1.E-5 ( $\text{m}^2/\text{s}$ ). If the diffusivity is above this threshold, then the program checks if the layer is sufficiently thick and may issue a warning if it is too thin and highly conductive.

The absorptance values in this object impart surface properties to the construction and should be applied to the thermally significant inner and outer layers in the overall assembly. Attempting to trick the program by modeling thin “paint” layers to apply surface properties is not a good idea; the models were not intended to support such strategies.

#### 1.9.3.1 Inputs

##### 1.9.3.1.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

#### 1.9.3.1.2 Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

#### 1.9.3.1.3 Field: Thickness

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive. **Modeling layers thinner (less) than 0.003 m is not recommended; rather, add those properties to one of the adjacent layers.**

#### 1.9.3.1.4 Field: Conductivity

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are W/(m-K). Thermal conductivity must be greater than zero. **Modeling layers with conductivity higher than 5.0 W/(m-K) is not recommended; however, this may be appropriate for non-surfaces such as pipes and TDDs (ref. DaylightingDevice:Tubular object).**

#### 1.9.3.1.5 Field: Density

This field is used to enter the density of the material layer in units of kg/m<sup>3</sup>. Density must be a positive quantity. **In some cases textbooks and references may use g/m<sup>3</sup>: be careful to not confuse units.**

#### 1.9.3.1.6 Field: Specific Heat

This field represents the specific heat of the material layer in units of J/(kg-K). Note that these units are most likely different than those reported in textbooks and references which tend to use kJ/(kg-K) or J/(g-K). They were chosen for internal consistency within EnergyPlus. **Only values of specific heat of 100 or larger are allowed. Typical ranges are from 800 to 2000 J/(kg-K).**

#### 1.9.3.1.7 Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength (>2.5 microns) radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions). The default value for this field is 0.9.

#### 1.9.3.1.8 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation (0.3 to 2.537 microns) includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat

balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

#### 1.9.3.1.9 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation (0.37 to 0.78 microns weighted by photopic response) is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

An IDF example:

```
Material,A2 - 4 IN DENSE FACE BRICK, ! Material Name
Rough, ! Roughness
0.1014984 , ! Thickness {m}
1.245296 , ! Conductivity {W/M*K}
2082.400 , ! Density {Kg/M**3}
920.4800 , ! Specific Heat {J/Kg*K}
0.9000000 , ! Thermal Absorptance
0.9300000 , ! Solar Absorptance
0.9300000 ; ! Visible Absorptance
```

### 1.9.4 Material:NoMass

Use this definition when only the thermal resistance (R value) of the material is known. This object is used to describe opaque construction elements.

#### 1.9.4.1 Inputs

##### 1.9.4.1.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

##### 1.9.4.1.2 Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A keyword is expected in this field with the options being “**VeryRough**”, “**Rough**”, “**MediumRough**”, “**MediumSmooth**”, “**Smooth**”, and “**VerySmooth**” in order of roughest to smoothest options.

##### 1.9.4.1.3 Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are (m<sup>2</sup>-K)/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

#### 1.9.4.1.4 Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength (>2.5 microns) radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions). The default value for this field is 0.9.

#### 1.9.4.1.5 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation (0.3 to 2.537 microns) includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

#### 1.9.4.1.6 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation (0.37 to 0.78 microns weighted by photopic response) is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

An IDF example:

```
Material:NoMass,R13LAYER, ! Material Name
Rough, ! Roughness
  2.290965 , ! Resistance {M**2K/W}
  0.9000000 , ! Thermal Absorptance
  0.7500000 , ! Solar Absorptance
  0.7500000 ; ! Visible Absorptance
```

### 1.9.5 Material:InfraredTransparent

A Infrared Transparent surface is similar to a resistance-only surface. The surface will actually participate in the transfer of visible and solar radiation by doing a wavelength transformation and making all short wave length radiation that is incident on the surface into long wave length radiation and having it participate in the long wavelength radiant exchange. **Note the ConvectionCoefficient instructions that follow the Infrared Transparent construction object below.**

### 1.9.5.1 Inputs

#### 1.9.5.1.1 Field: Name

This field contains the unique name (across all Material objects) for the Infrared Transparent material.

A Infrared Transparent surface should not participate in a convective/conductive exchange between the zones it separates. In order to minimize this effect, the ConvectionCoefficients object must be used for the surfaces referencing the Infrared Transparent (IRT) construction.

An example idf object specification for use with the IRT surface is shown below. Note that surfaces are not described in this example

```

Material:InfraredTransparent,
  IRTMaterial1;          !- Name

Construction,
  IRTSurface,           !- Name
  IRTMaterial1;         !- Outside Layer

SurfaceProperty:ConvectionCoefficients,
  Bottom:Top,           !- SurfaceName
  Outside,              !- Convection Type 1
  value,                !- Convection Value Type 1
  0.1,                  !- Convection value 1 {W/m2-K}
  ,                     !- Convection Schedule 1
  Inside,               !- Convection Type 2
  value,                !- Convection Value Type 2
  0.1;                  !- Convection value 2 {W/m2-K}

SurfaceProperty:ConvectionCoefficients,
  SecondLevel:Bottom,   !- SurfaceName
  Outside,              !- Convection Type 1
  value,                !- Convection Value Type 1
  0.1,                  !- Convection value 1 {W/m2-K}
  ,                     !- Convection Schedule 1
  Inside,               !- Convection Type 2
  value,                !- Convection Value Type 2
  0.1;                  !- Convection value 2 {W/m2-K}

SurfaceProperty:ConvectionCoefficients,
  SecondLevel:Top,      !- SurfaceName
  Outside,              !- Convection Type 1
  value,                !- Convection Value Type 1
  0.1,                  !- Convection value 1 {W/m2-K}
  ,                     !- Convection Schedule 1
  Inside,               !- Convection Type 2
  value,                !- Convection Value Type 2
  0.1;                  !- Convection value 2 {W/m2-K}

SurfaceProperty:ConvectionCoefficients,
  ThirdLevel:Bottom,    !- SurfaceName
  Outside,              !- Convection Type 1
  value,                !- Convection Value Type 1
  0.1,                  !- Convection value 1 {W/m2-K}
  ,                     !- Convection Schedule 1
  Inside,               !- Convection Type 2
  value,                !- Convection Value Type 2
  0.1;                  !- Convection value 2 {W/m2-K}

```

## 1.9.6 Material:AirGap

This material is used to describe the air gap in an opaque construction element. Glass elements use a different property (WindowGas) to describe the air between two glass layers.

### 1.9.6.1 Inputs

#### 1.9.6.1.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

#### 1.9.6.1.2 Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are ( $m^2 \cdot K$ )/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

An IDF example:

```
Material:AirGap,B1 - AIRSPACE RESISTANCE, ! Material Name
 0.1603675 ; ! Resistance {M**2K/W}
```

## 1.9.7 MaterialProperty:MoisturePenetrationDepth:Settings

This material is used to describe the nine moisture material properties that are used in the EMPD (Effective Moisture Penetration Depth) heat balance solution algorithm. The EMPD algorithm is a simplified, lumped moisture model that simulates moisture storage and release from interior surfaces. The model uses convective mass transfer coefficients that are determined by existing heat and mass transfer relationships, e.g. the Lewis relation. The EMPD model includes two fictitious layers of material with uniform moisture content: a surface layer, which accounts for short-term moisture buffering, and a deep layer, which accounts for more slowly responding moisture buffering. The model calculates the moisture transfer between the air and the surface layer and between the surface layer and the deep layer. This moisture transfer impacts the zone humidity, and also impacts the zone temperature through latent-to-sensible conversion from the heat of adsorption.

This moisture model is used when the appropriate EMPD moisture materials are specified and the Solution Algorithm parameter is set to MoisturePenetrationDepthConductionTransferFunction.

### 1.9.7.1 Inputs

#### 1.9.7.1.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

#### 1.9.7.1.2 Field: Water Vapor Diffusion Resistance Factor

The vapor diffusion resistance factor is the resistance to water vapor diffusion *relative* to the resistance to water vapor diffusion in stagnant air. In other words,  $\mu$  equals 1 for air, and is generally greater than 1 for building materials.

The equation for  $\mu$  is:

$$\mu = \frac{\delta_{perm,air}}{\delta_{perm}}$$

where  $\delta_{perm,air}$  is the permeability of water vapor in air [kg/m-s-Pa], and  $\delta_{perm}$  is the permeability of water vapor in the material. The permeability of water vapor in air can be estimated as:

$$\delta_{perm,air} = \frac{2 \times 10^{-7} \cdot T^{0.81}}{P_{ambient}}$$

where  $T$  is the temperature [C] and  $P_{ambient}$  the ambient atmospheric pressure [Pa].

#### 1.9.7.1.3 Fields: Moisture equilibrium constants

The next four fields, coefficients  $a$ ,  $b$ ,  $c$ , and  $d$ , define the sorption isotherm curve used for building materials under equilibrium conditions. They define the relationship between the material's moisture content and the surface air relative humidity (ref: Effective Moisture Penetration Depth (EMPD) Model in the Engineering Reference):

$$u = a \cdot \phi^b + c \cdot \phi^d$$

where

$a, b, c, d$  = Coefficients to define the relationship between the material's moisture content and the surface air relative humidity

$u$  = Moisture content defined as the mass fraction of water contained in a material, per mass of dry material [kg/kg]

$\phi$  = Surface air relative humidity [0 to 1],

#### 1.9.7.1.4 Field: Surface Layer Penetration Depth

The Surface Layer Penetration Depth is the fictitious thickness of the surface layer in meters, and is used to calculate the volume of material that participates in short-term moisture transfer and storage. This layer has a uniform moisture content, and can be considered a *lumped-capacitance*. The penetration depth is based on the amount of material that interacts with the zone air when subject to a cyclic relative humidity variation. It also impacts the mass transfer resistance between the zone air and this layer, with thinner depths resulting in lower mass transfer resistances (ref: Effective Moisture Penetration Depth (EMPD) Model in the Engineering Reference). For this reason very small values can lead to instabilities depending on the timestep. The surface penetration depth can be estimated with the following equation:

$$d_{EMPD,surf} = \sqrt{\frac{\delta_{perm} P_{sat} \tau_{surf}}{\rho_{material} \frac{du}{d\phi} \pi}}$$

where

$\delta_{perm}$  = water vapor permeability in the material, kg/m-s-Pa (see Vapor diffusion resistance factor above)

$P_{sat}$  = saturated vapor pressure at some nominal temperature, Pa

$\tau_{surf}$  = cycle period of typical RH variations, s. 24 hours (87600 s) is often used.

$\rho_{material}$  = dry density of material, kg/m<sup>3</sup>

$\frac{du}{d\phi}$  = slope of moisture sorption curve,  $ab\phi^{b-1} + cd\phi^{d-1}$

If this field is left blank or set to **autocalculate**, the above equation will be used to calculate the surface layer penetration depth assuming a  $\tau_{surf}$  of 24 hours. To use a period different than 24 hours, the equation above can be used to calculate the penetration depth based on a different value of  $\tau_{surf}$ . The penetration depth can also be entered as an empirical value, as in [Woods and Winkler, 2016](#). If calculating  $d_{EMPD,surf}$ , the assumed value of  $\tau_{surf}$  should not be less than 4x the simulation timestep to ensure an accurate and stable solution.

#### 1.9.7.1.5 Field: Deep Layer Penetration Depth

The Deep Layer Penetration Depth is the fictitious thickness of the deep layer in meters, and is used to calculate the volume of material that participates in long-term moisture transfer and storage. This layer has a uniform moisture content, and can be considered a *lumped-capacitance*. The deep penetration depth is based on the amount of material that interacts with the surface layer when subject to cyclic relative humidity variation. The deep penetration depth can be estimated with the following equation:

$$d_{EMPD,deep} = \sqrt{\frac{\delta_{perm} P_{sat} \tau_{deep}}{\rho_{material} \frac{du}{d\phi} \pi}}$$

where each term is the same as the surface layer, except that the cycle period is different. This is usually on the order of weeks for the deep layer.

If this field is left blank or set to **autocalculate**, the above equation will be used to calculate the deep layer penetration depth assuming a  $\tau_{deep}$  of three weeks. To use a period different than 3 weeks, the equation above can be used to calculate the penetration depth based on a different value of  $\tau_{deep}$ . The penetration depth can also be entered as an empirical value, as in [Woods and Winkler, 2016](#).

#### 1.9.7.1.6 Field: Coating Layer Thickness

The Coating Layer Thickness (in meters) adds an additional resistance between the surface layer and the zone and represents a thin coating, such as paint, plaster, or other wall coverings.

This input is optional, and an input of zero implies no coating.

#### 1.9.7.1.7 Field: Coating Layer Water Vapor Diffusion Resistance Factor

The vapor diffusion resistance factor of the coating is the coating's resistance to water vapor diffusion *relative* to the resistance to water vapor diffusion in stagnant air (see Vapor diffusion resistance factor section above).

This input is optional, and an input of zero implies no coating.

Below are two IDF examples:

This set of inputs can be used for aerated concrete (assuming linear sorption curve). Density, input elsewhere, is 650 kg/m<sup>3</sup>:

```
MaterialProperty:MoisturePenetrationDepth:Settings,
Concrete,          !- Name
6.55,              !- Water Vapor Diffusion Resistance Factor {dimensionless}
0.066,             !- Moisture Equation Coefficient a {dimensionless}
1,                 !- Moisture Equation Coefficient b {dimensionless}
0,                 !- Moisture Equation Coefficient c {dimensionless}
1,                 !- Moisture Equation Coefficient d {dimensionless}
0.007,             !- Surface Layer Penetration Depth {m}
0.024,             !- Deep Layer Penetration Depth {m}
0,                 !- Coating Layer Thickness {m}
```

```
1;           !- Coating Layer Water Vapor Diffusion Resistance Factor {dimensionless}
```

This set of inputs is for gypsum board with density 750 kg/m<sup>3</sup>. This also assumes 2 coats of latex paint:

```
MaterialProperty:MoisturePenetrationDepth:Settings,
Concrete,          !- Name
6.0,               !- Water Vapor Diffusion Resistance Factor {dimensionless}
0.0065,            !- Moisture Equation Coefficient a {dimensionless}
0.65,              !- Moisture Equation Coefficient b {dimensionless}
0.022,             !- Moisture Equation Coefficient c {dimensionless}
10,                !- Moisture Equation Coefficient d {dimensionless}
0.021,             !- Surface Layer Penetration Depth {m}
0.08,              !- Deep Layer Penetration Depth {m}
0.0003,            !- Coating Layer Thickness {m}
6000;              !- Coating Layer Water Vapor Diffusion Resistance Factor {dimensionless}
```

Finally, here are values representing the empirical whole-house inputs from Woods et al., 2014 (see Engineering Reference). Density is 800 kg/m<sup>3</sup>:

```
MaterialProperty:MoisturePenetrationDepth:Settings,
Concrete,          !- Name
8.0,               !- Water Vapor Diffusion Resistance Factor {dimensionless}
0.012,             !- Moisture Equation Coefficient a {dimensionless}
1,                 !- Moisture Equation Coefficient b {dimensionless}
0,                 !- Moisture Equation Coefficient c {dimensionless}
1,                 !- Moisture Equation Coefficient d {dimensionless}
0.019,             !- Surface Layer Penetration Depth {m}
0.113,             !- Deep Layer Penetration Depth {m}
0,                 !- Coating Layer Thickness {m}
1;                 !- Coating Layer Water Vapor Diffusion Resistance Factor {dimensionless}
```

Other materials inputs can be estimated using the equations above and material properties from a variety of sources, such as *Kumaran, 1996*, the *WUFI* simulation software, or the *ASHRAE 1018-RP* report.

### 1.9.7.2 Outputs

#### 1.9.7.2.1 EMPD Surface Inside Face Water Vapor Density [kg/m<sup>3</sup>]

The vapor density at the inside face of the surface, where the EMPD moisture balance solution algorithm is applied. This is the *actual* surface, separated from the zone air only by the convective mass transfer coefficient.

Units are kg of water per cubic meter of air.

#### 1.9.7.2.2 EMPD Surface Layer Moisture Content [kg/kg]

The moisture content,  $u$ , of the fictitious surface layer. The surface layer node is not at the actual surface, but is instead at the center of surface layer, which has a uniform moisture content. This node is separated from the inside face of the surface by a diffusive resistance, as described in the Engineering Reference.

Units are kg of water per kg of solid material (e.g., gypsum).

#### 1.9.7.2.3 EMPD Deep Layer Moisture Content [kg/kg]

The moisture content,  $u$ , of the fictitious deep layer. The deep layer node interacts only with the surface layer node through a diffusive resistance.

Units are kg of water per kg of solid material.

**1.9.7.2.4 EMPD Surface Layer Equivalent Relative Humidity [%]**

The equivalent relative humidity of the surface layer, converted from the surface-layer moisture content discussed above and the surface temperature. The moisture content is related to the relative humidity through the slope of the moisture curve, the surface penetration depth, and the material density, as discussed in the engineering reference.

**1.9.7.2.5 EMPD Deep Layer Equivalent Relative Humidity [%]**

The equivalent relative humidity of the deep layer, converted from the deep-layer moisture content discussed above and the surface temperature.

**1.9.7.2.6 EMPD Surface Layer Equivalent Humidity Ratio [kgWater/kgDryAir]**

The equivalent humidity ratio of the surface layer. Units are kg of water per kg of dry air.

**1.9.7.2.7 EMPD Deep Layer Equivalent Humidity Ratio [kgWater/kgDryAir]**

The equivalent humidity ratio of the deep layer. Units are kg of water per kg of dry air.

**1.9.7.2.8 EMPD Surface Moisture Flux to Zone [kg/m<sup>2</sup>-s]**

The mass flux of water vapor from the surface layer of a specific surface to the zone air. A positive mass flux is from the surface to the zone.

**1.9.7.2.9 EMPD Deep Layer Moisture Flux [kg/m<sup>2</sup>-s]**

The mass flux of water vapor from the deep layer of a specific surface to the surface layer of that surface. A positive flux is from the surface layer to the deep layer.

## 1.9.8 MaterialProperty:PhaseChange

**Advanced/Research Usage:** This material is used to describe the temperature dependent material properties that are used in the Conduction Finite Difference solution algorithm. This conduction model is done when the appropriate materials are specified and the Solution Algorithm parameter is set toConductionFiniteDifference. This permits simulating temperature dependent thermal conductivity and phase change materials (PCM) in EnergyPlus.

### 1.9.8.1 Inputs

#### 1.9.8.1.1 Field: Name

This field is a regular material name specifying the material with which this additional temperature dependent property information will be associated.

#### 1.9.8.1.2 Field: Temperature Coefficient for Thermal Conductivity

This field is used to enter the temperature dependent coefficient for thermal conductivity of the material. Units for this parameter are (W/(m-K<sup>2</sup>)). This is the thermal conductivity change per unit temperature excursion from 20 C. The conductivity value at 20 C is the one specified with the basic material properties of the regular material specified in the name field. The thermal conductivity is obtained from:

$$k = k_o + k_1(T_i - 20) \quad (1.13)$$

where:

$k_o$  is the 20C value of thermal conductivity(normal idf input)

$k_1$  is the change in conductivity per degree temperature difference from 20C

#### 1.9.8.1.3 Field Set: Temperature-Enthalpy

The temperature – enthalpy set of inputs specify a two column tabular temperature-enthalpy function for the basic material. Sixteen pairs can be specified. Specify only the number of pairs necessary. The tabular function must cover the entire temperature range that will be seen by the material in the simulation. It is suggested that the function start at a low temperature, and extend to 100C. Note that the function has no negative slopes and the lowest slope that will occur is the base material specific heat. Temperature values should be strictly increasing. Enthalpy contributions of the phase change are always added to the enthalpy that would result from a constant specific heat base material. An example of a simple enthalpy temperature function is shown below.

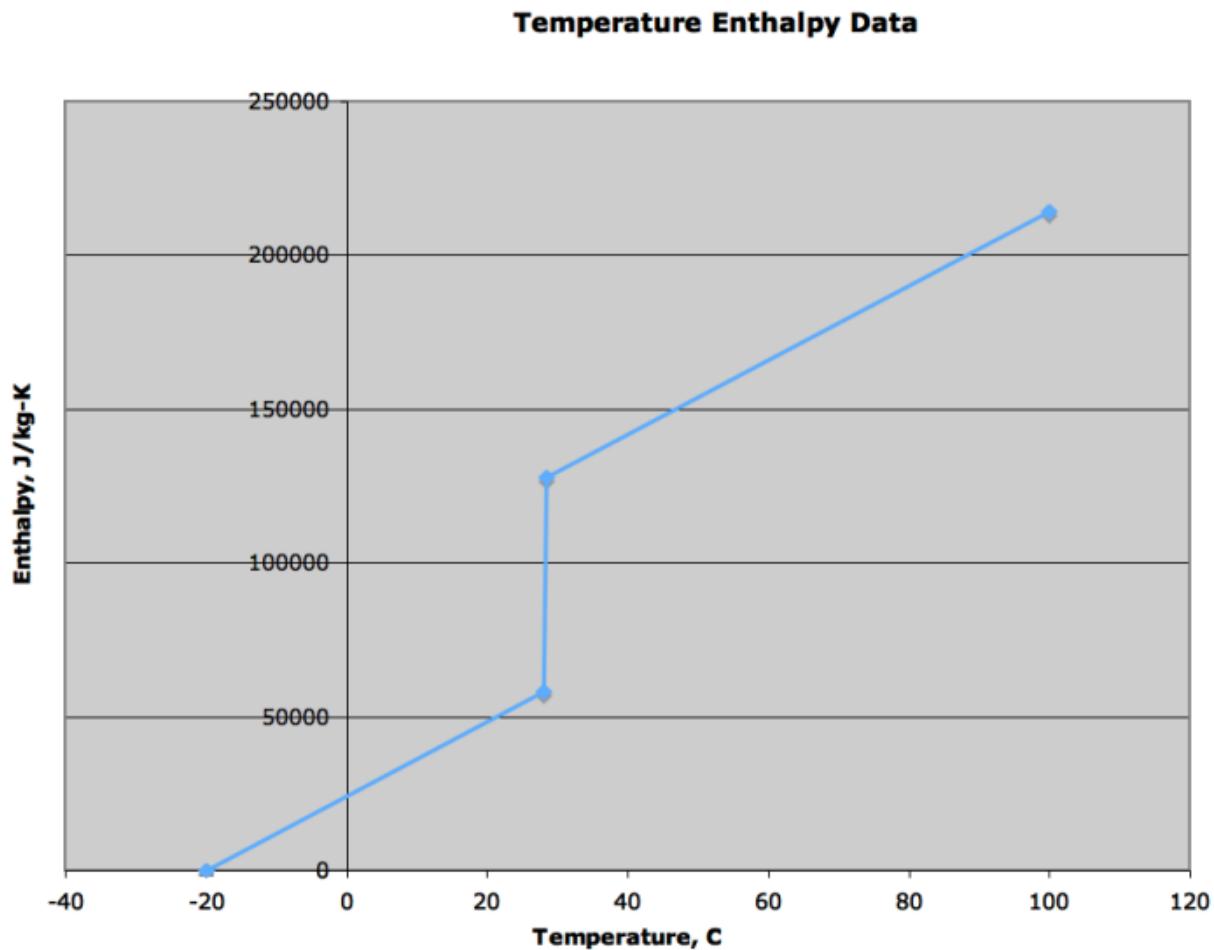

Figure 1.11: Temp-Enth Example

#### 1.9.8.1.4 Field: Temperature x

This field is used to specify the temperature of the temperature-enthalpy function for the basic material. Units are C.

#### 1.9.8.1.5 Field: Enthalpy x

This field specifies the enthalpy that corresponds to the previous temperature of the temperature-enthalpy function. Units are J/kg.

And, an IDF example showing how it is used in conjunction with the Material:

Note, the following Heat Balance Algorithm is necessary (only specified once). Also, when using ConductionFiniteDifference, it is more efficient to set the zone timestep shorter than those used for the ConductionTransferFunction solution algorithm. It should be set to 12 timesteps per hour or greater, and can range up to 60.

### 1.9.9 MaterialProperty:PhaseChangeHysteresis

This object is used to describe an advanced level of physics belonging to phase change materials used in building envelopes. The base phase change input object describes a single process curve whereby a material moves from a crystallized to liquid state and back. This input object adds a hysteresis effect, allowing the melting/freezing process to follow different curves, representing an effect that is commonly seen in actual building envelope phase change material applications. This object also allows users to enter characteristic properties of the processes instead of a detailed temperature/enthalpy curve, making it more amenable for studies in which the user does not have the detailed test data required to generate the temperature/enthalpy curve. For more information

on the use of phase change materials (PCM) with hysteresis, see the Conduction Finite Difference Solution Algorithm section of the EnergyPlus Engineering Reference document.

### 1.9.9.1 Inputs

The `MaterialProperty:PhaseChangeHysteresis` object includes the following inputs. For the characteristic curve properties, see the engineering reference.

#### 1.9.9.1.1 Field: Name

This input must match the name of a material defined elsewhere within EnergyPlus. The thermal properties of that material are then overridden by the properties defined in this object.

#### 1.9.9.1.2 Field: Latent Heat during the Entire Phase Change Process

This is the total amount of latent heat absorbed or discharged during the transition from solid to liquid or back, in Joules. The shapes of the enthalpy curves differ based on direction, but the total amount of energy from one state to the other does not.

#### 1.9.9.1.3 Field: Liquid State Thermal Conductivity

This is the constant thermal conductivity used while the material is fully liquid, in W/m-K.

#### 1.9.9.1.4 Field: Liquid State Density

This is the constant density while the material is fully liquid, in kg/m<sup>3</sup>.

#### 1.9.9.1.5 Field: Liquid State Specific Heat

This is the constant specific heat while the material is fully liquid, in J/kg-K.

#### 1.9.9.1.6 Field: High Temperature Difference of Melting Curve

This is the width of the enthalpy/specific heat melting curve, on the high side of the peak melting temperature, in Celsius (technically it is “change in Celsius”).

#### 1.9.9.1.7 Field: Peak Melting Temperature

This is the center (peak) of the melting curve, in Celsius.

#### 1.9.9.1.8 Field: Low Temperature Difference of Melting Curve

This is the width of the enthalpy/specific heat melting curve, on the low side of the peak melting temperature, in Celsius (technically it is “change in Celsius”).

#### 1.9.9.1.9 Field: Solid State Thermal Conductivity

This is the constant thermal conductivity used while the material is fully solid, in W/m-K.

#### 1.9.9.1.10 Field: Solid State Density

This is the constant density while the material is fully solid, in kg/m<sup>3</sup>.

#### 1.9.9.1.11 Field: Solid State Specific Heat

This is the constant specific heat while the material is fully crystallized, in J/kg-K.

#### 1.9.9.1.12 Field: High Temperature Difference of Freezing Curve

This is the width of the enthalpy/specific heat freezing curve, on the high side of the peak freezing temperature, in Celsius (technically it is “change in Celsius”).

#### 1.9.9.1.13 Field: Peak Freezing Temperature

This is the center (peak) of the freezing curve, in Celsius. This will generally be lower than the peak melting temperature based on empirical data. Note, however, that EnergyPlus does allow users to specify a peak freezing temperature that is higher than the peak melting temperature.

#### 1.9.9.1.14 Field: Low Temperature Difference of Freezing Curve

This is the width of the enthalpy/specific heat freezing curve, on the low side of the peak freezing temperature, in Celsius (technically it is “change in Celsius”).

An IDF example using hysteresis in conjunction with an actual Material definition is shown below. This example includes the specification of the Heat Balance Algorithm and Timestep to show appropriate values for these inputs when MaterialProperty:PhaseChangeHysteresis is used. Heat Balance Algorithm and Timestep are only specified once in a particular idf file. Note that when using ConductionFiniteDifference, it is more efficient to set the zone timestep shorter than those used for the ConductionTransferFunction solution algorithm. It should be set to 12 timesteps per hour or greater and can range up to 60.

```

#### 1.9.9.2 Outputs

The **MaterialProperty:PhaseChangeHysteresis** object also includes the following outputs. The Conduction Finite Difference solution algorithm uses a finite difference solution technique where

the surfaces are divided into a nodal arrangement. These outputs are specific to Conduction Finite Difference solution.

The following output variables are applicable to all opaque heat transfer surfaces when using Solution Algorithms ConductionFiniteDifference. Note that the “X” in the list and descriptions below must be replaced by a number that indicates the node at which the variables are being reported. So, for example, to report the surface temperature for node 7, one would use “CondFD Surface Temperature Node 7”.

- Zone,Average,CondFD Phase Change State <X> []
- Zone,Average,CondFD Phase Change Previous State <X> []
- Zone,Average,CondFD Phase Change Node Temperature <X> [C]
- Zone,Average,CondFD Phase Change Node Conductivity <X> [W/m-K]
- Zone,Average,CondFD Phase Change Node Specific Heat <X> [J/kg-K]

#### **1.9.9.2.1 CondFD Phase Change State []**

This outputs the current phase classification for the node. The values for this output relate to the following phase categories:

- -2 = liquid
- -1 = melting
- 0 = transition
- 1 = freezing
- 2 = crystallized

#### **1.9.9.2.2 CondFD Phase Change Previous State []**

This outputs the previous phase classification for the node. The values for this output are the same as for the output CondFD Phase Change State above.

#### **1.9.9.2.3 CondFD Phase Change Node Temperature <X> [C]**

This will output temperatures for a node in the surfaces being simulated with ConductionFiniteDifference. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file. This output is specific to surfaces that use the Conduction Finite Difference solution technique and have a [MaterialProperty:PhaseChangeHysteresis](#) object in the input file. The units for this output field are degrees Celsius.

#### **1.9.9.2.4 CondFD Phase Change Node Conductivity <X> [W/m-K]**

This will output the conductivity for a node in the surfaces being simulated with ConductionFiniteDifference. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file. This output is specific to surfaces that use the Conduction Finite Difference solution technique and have a [MaterialProperty:PhaseChangeHysteresis](#) object in the input file. The units for this output field are W/m-K.

### 1.9.9.2.5 CondFD Phase Change Node Specific Heat <X> [J/kg-K]

This will output the specific heat for a node in the surfaces being simulated with ConductionFiniteDifference. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file. This output is specific to surfaces that use the Conduction Finite Difference solution technique and have a [MaterialProperty:PhaseChangeHysteresis](#) object in the input file. The units for this output field are J/kg-K.

## 1.9.10 MaterialProperty:VariableThermalConductivity

This object is used to describe the temperature dependent material properties that are used in the CondFD (Conduction Finite Difference) solution algorithm. This conduction model is used when the appropriate CondFD materials are specified and the Solution Algorithm parameter is set to condFD.

### 1.9.10.1 Inputs

#### 1.9.10.1.1 Field: Name

This field is a regular material name specifying the material with which this additional temperature dependent property information will be associated.

#### 1.9.10.1.2 Field Set: Temperature-Thermal Conductivity

The temperature – conductivity set of inputs specify a two column tabular temperature-thermal conductivity function for the basic material. Ten pairs can be specified. Specify only the number of pairs necessary. Temperature values should be strictly increasing.

#### 1.9.10.1.3 Field: Temperature x

This field is used to specify the temperature of the temperature-conductivity function for the basic material. Units are C.

#### 1.9.10.1.4 Field: Thermal Conductivity x

This field specifies the conductivity that corresponds to the temperature (previous field) of the temperature-conductivity function. Units are W/m-K.

And, an IDF example showing how it is used in conjunction with the Materials:

Note, the following Heat Balance Algorithm is necessary (only specified once). Also, when using Conduction Finite Difference, it is more efficient to set the zone time step shorter than those used for the Conduction Transfer Function solution algorithm. It should be set to 12 time steps per hour or greater, and can range up to 60.

### 1.9.10.2 Outputs

The Conduction Finite Difference solution algorithm uses a finite difference solution technique where the surfaces are divided into a nodal arrangement. These outputs are specific to Conduction Finite Difference solution.

The following output variables are applicable to all opaque heat transfer surfaces when using Solution Algorithms ConductionFiniteDifference. Note that the “X” in the list and descriptions below must be replaced by a number that indicates the Node at which the variables are being reported. So, for example, to report the surface temperature for node 7, one would use “CondFD Surface Temperature Node 7”.

- Zone,Sum,CondFD Inner Solver Loop Iteration Count []
- Zone,Average,CondFD Surface Temperature Node <X> [C]
- Zone,Average,CondFD Surface Heat Flux Node <X> [W/m<sup>2</sup>]
- Zone,Average,CondFD Surface Heat Capacitance Outer Half Node <X> [W/m<sup>2</sup>-K]
- Zone,Average,CondFD Surface Heat Capacitance Inner Half Node <X> [W/m<sup>2</sup>-K]

#### 1.9.10.2.1 CondFD Inner Solver Loop Iteration Count []

This outputs the count of iterations on the inner solver loop of CondFD for each surface.

#### 1.9.10.2.2 CondFD Surface Temperature Node <X> [C]

This will output temperatures for a node in the surfaces being simulated with ConductionFiniteDifference. The key values for this output variable are the surface name. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file.

#### 1.9.10.2.3 CondFD Surface Heat Flux Node <X> [W/m<sup>2</sup>]

This will output heat flux at each node in surfaces being simulated with ConductionFiniteDifference. The key values for this output variable are the surface name. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file. A positive value indicates

heat flowing towards the inside face of the surface. Note that this matches the sign convention for Surface Inside Face Conduction Heat Transfer Rate per Area and is opposite the sign of Surface Outside Face Conduction Heat Transfer Rate per Area.

#### 1.9.10.2.4 CondFD Surface Heat Capacitance Outer Half Node <X> [W/m<sup>2</sup>-K]

#### 1.9.10.2.5 CondFD Surface Heat Capacitance Inner Half Node <X> [W/m<sup>2</sup>-K]

These will output the half-node heat capacitance in surfaces being simulated with ConductionFiniteDifference. The key values for this output variable are the surface name. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file. For this output, the heat capacitance is defined as the product of specific heat, density, and node thickness. Zero is reported for R-layer half-nodes and for undefined half-nodes. There is no outer half-node for Node 1 which is the outside face of the surface, and there is no inner half-node for Node N which is the inside face of the surface. CondFD Surface Heat Capacitance is only available when the user includes a Output:Diagnostics, DisplayAdvancedReportVariables designation in the input file.

### 1.9.11 MaterialProperty:HeatAndMoistureTransfer:Settings

**Advanced/Research Usage:** This object is used to describe two of the seven additional material properties needed for the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm. The settings object is used when the solutions algorithm is set to CombinedHeatAndMoistureFiniteElement and the appropriate material properties are assigned to each material. This permits the simulation of the moisture dependent thermal properties of the material as well as the transfer of moisture through, into and out of the material into the zone or exterior.

In addition to the Porosity and Initial Water content properties described here, five additional properties, described by tabulated relationships between variables, are required. These properties are;

- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

All materials in a construction are required to have all material properties defined for HAMT to work.

Within the MaterialProperty:HeatAndMoistureTransfer:Settings object the following fields are defined.

### 1.9.11.1 Inputs

#### 1.9.11.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.9.11.1.2 Field: Porosity

The porosity of a material is the maximum fraction, by volume, of a material that can be taken up with water. The units are [m<sup>3</sup>/m<sup>3</sup>].

#### 1.9.11.1.3 Field: Initial Water Content Ratio

For this solution algorithm, the initial water content is assumed to be distributed evenly through the depth of the material. The units are [kg/kg].

Below is an example input for the porosity and initial water content of a material.

```
MaterialProperty:HeatAndMoistureTransfer:Settings,
  Concrete,      !- Name
  0.76,          !- Porosity
  0.2;           !- Initial (or typical) Water content
```

### 1.9.12 MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The Isotherm data relates the moisture, or water content [kg/m<sup>3</sup>] of a material with the relative humidity (RH). The water content is expected to increase as relative humidity increases, starting at zero content at 0.0 relative humidity fraction and reaching a maximum, defined by the porosity, at 1.0 relative humidity fraction, which corresponds to 100% relative humidity. Relative humidities are entered as fraction for this object ranging from 0.0 to 1.0. These two extremes (0.0 and 1.0) are automatically set by the HAMT solution. However, if they are entered they will be used as extra data points. Data should be provided with increasing RH and moisture content up to as high an RH as possible to provide a stable solution. One possible reason for the following error message may be that a material has a very rapid increase in water content for a small change in RH, which can happen if the last entered water content point is at a low RH and the material has a very high porosity.

```
** Warning ** HeatAndMoistureTransfer: Large Latent Heat for Surface ROOF
```

Another potential reason for this error being generated is the use of inappropriate values for Vapor Transfer Coefficients. See the [SurfaceProperties:VaporCoefficients](#) object in the Advanced Surface Concepts group.

### 1.9.12.1 Inputs

#### 1.9.12.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

### 1.9.12.1.2 Field: Number of data Coordinates

A maximum of 25 coordinates can be specified.

### 1.9.12.1.3 Field Set: Relative Humidity-Moisture Content

#### 1.9.12.1.4 Field: Relative Humidity Fraction x

The relative humidity of the  $x^{th}$  coordinate. The relative humidity is entered as fraction, not in percent.

#### 1.9.12.1.5 Field: Moisture Content x

The Moisture Content of the  $x^{th}$  coordinate. The units are [kg/m<sup>3</sup>]

Below is an example input for a material isotherm

```
MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm,
  Concrete,      !- Name
  10,           !- Number of data Coordinates
  0.2205,       !- Relative Humidity fraction #1
  22.31,        !- Moisture content #1
  0.202,        !- Relative Humidity fraction #2
  19.665,       !- Moisture content #2
  0.449,        !- Relative Humidity fraction #3
  40.02,        !- Moisture content #3
  0.454,        !- Relative Humidity fraction #4
  36.915,       !- Moisture content #4
  0.6506,       !- Relative Humidity fraction #5
  56.005,       !- Moisture content #5
  0.655,        !- Relative Humidity fraction #6
  52.325,       !- Moisture content #6
  0.824,        !- Relative Humidity fraction #7
  72.565,       !- Moisture content #7
  0.8725,       !- Relative Humidity fraction #8
  85.1,         !- Moisture content #8
  0.924,        !- Relative Humidity fraction #9
  91.08,        !- Moisture content #9
  0.964,        !- Relative Humidity fraction #10
  100.28;       !- Moisture content #10
```

## 1.9.13 MaterialProperty:HeatAndMoistureTransfer:Suction

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The suction data relates the liquid transport coefficient, under suction, to the water content of a material. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by HAMT when the rain flag is set in the weather file.

### 1.9.13.1 Inputs

#### 1.9.13.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

### 1.9.13.1.2 Field: Number of Suction points

A maximum of 25 points can be specified.

### 1.9.13.1.3 Field Set: Moisture Content-Liquid Transport Coefficient

#### 1.9.13.1.4 Field: Moisture Content x

The moisture content of the  $x^{th}$  point. The units are [kg/m<sup>3</sup>].

#### 1.9.13.1.5 Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the  $x^{th}$  point. The units are [m<sup>2</sup>/s].

Below is an example input for a material liquid transport coefficient under suction.

```
MaterialProperty:HeatAndMoistureTransfer:Suction,
  Concrete,      !- Name
  5,            !- Number of Suction points
  0,            !- Moisture content 1
  0,            !- Liquid Transport Coefficient 1
  72,           !- Moisture content 2
  0.000000000741,       !- Liquid Transport Coefficient 2
  85,           !- Moisture content 3
  0.000000000253,       !- Liquid Transport Coefficient 3
  100,          !- Moisture content 4
  0.0000000101,       !- Liquid Transport Coefficient 4
  118,          !- Moisture content 5
  0.0000000128;       !- Liquid Transport Coefficient 5
```

## 1.9.14 MaterialProperty:HeatAndMoistureTransfer:Redistribution

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The redistribution data relates the liquid transport coefficient to the water content of a material under normal conditions. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by the Heat and Moisture Transfer algorithm when the rain flag is NOT set in the weather file.

### 1.9.14.1 Inputs

#### 1.9.14.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.9.14.1.2 Field: Number of Redistribution points

A maximum of 25 points can be specified.

#### 1.9.14.1.3 Field Set: Moisture Content– Liquid Transport Coefficient

#### 1.9.14.1.4 Field: Moisture Content x

The moisture content of the  $x^{th}$  point. The units are [kg/m<sup>3</sup>].

#### 1.9.14.1.5 Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the  $x^{th}$  point. The units are [m<sup>2</sup>/s].

Below is an example input for the object.

```
MaterialProperty:HeatAndMoistureTransfer:Redistribution,
  Concrete,      !- Name
  5,            !- Number of Redistribution points
  0,            !- Moisture content 1
  0,            !- Liquid Transport Coefficient 1
  72,           !- Moisture content 2
  0.0000000000741,     !- Liquid Transport Coefficient 2
  85,           !- Moisture content 3
  0.000000000253,     !- Liquid Transport Coefficient 3
  100,          !- Moisture content 4
  0.000000000101,     !- Liquid Transport Coefficient 4
  118,          !- Moisture content 5
  0.000000000128;     !- Liquid Transport Coefficient 5
```

---

#### 1.9.15 MaterialProperty:HeatAndMoistureTransfer:Diffusion

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The MU data relates the vapor diffusion resistance factor (dimensionless) to the relative humidity as fraction(RH). A data point at zero RH is required. The vapor diffusion resistance factor at the highest entered relative humidity (RH) value is used for all vapor diffusion resistance factor values above this RH. The relative humidity maximum value in fraction is 1.0.

##### 1.9.15.1 Inputs

###### 1.9.15.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

###### 1.9.15.1.2 Field: Number of Data Pairs

A maximum of 25 pairs can be specified.

###### 1.9.15.1.3 Field Set: Relative Humidity-Vapor Diffusion Resistance Factor

###### 1.9.15.1.4 Field: Relative Humidity Fraction #x

The moisture content of the  $x^{th}$  pair. The relative humidity is entered as fraction, not in percent.

###### 1.9.15.1.5 Field: Vapor Diffusion Resistance Factor #x

The Liquid Transport Coefficient of the  $x^{th}$  pair.

Below are some examples of the values for materials.

```
MaterialProperty:HeatAndMoistureTransfer:Diffusion,
  Plywood,      !- Name
  3,            !- Number of data Points
  0,            !- Relative Humidity Fraction 1
  700,          !- Water Vapor Diffusion Resistance Factor 1
  0.5,          !- Relative Humidity Fraction 2
  200,          !- Water Vapor Diffusion Resistance Factor 2
```

```

1,      !- Relative Humidity Fraction 3
20;     !- Water Vapor Diffusion Resistance Factor 3

MaterialProperty:HeatAndMoistureTransfer:Diffusion,
Concrete,      !- Name
1,      !- Number of Mu Points
0,      !- Relative Humidity Fraction 1
180;     !- Water Vapor Diffusion Resistance Factor 1

```

---

## 1.9.16 MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The thermal data relates the thermal conductivity [W/m-K] of a material to the moisture or water content [kg/m<sup>3</sup>]. A data point at zero water content is required. The thermal conductivity at the highest entered water content value is used for all thermal conductivity values above this water content. If this object is not defined for a material then the algorithm will use a constant value entered in the Material object for all water contents.

### 1.9.16.1 Inputs

#### 1.9.16.1.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.9.16.1.2 Field: Number of Thermal Coordinates

A maximum of 25 coordinates can be specified.

#### 1.9.16.1.3 Field Set: Moisture Content- Thermal Conductivity

#### 1.9.16.1.4 Field: Moisture Content x

The moisture content of the x<sup>th</sup> coordinate. The units are [kg/m<sup>3</sup>]

#### 1.9.16.1.5 Field: Thermal Conductivity x

The Thermal Conductivity of the x<sup>th</sup> coordinate. The units are [W/m-K]

Below is an example of values for a material.

```

MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity
Concrete,      !- Name
2,      !- Number of Thermal Coordinates
0,      !- Moisture content \#1
1.6,     !- Thermal Conductivity \#1
180,     !- Moisture content \#2
2.602;   !- Thermal Conductivity \#2

```

---

### 1.9.16.2 Surface Outputs

- Zone,Average,HAMT Surface Average Water Content Ratio [kg/kg]
- Zone,Average,HAMT Surface Inside Face Temperature [C]

- Zone,Average,HAMT Surface Inside Face Relative Humidity [%]
- Zone,Average,HAMT Surface Inside Face Vapor Pressure [Pa]
- Zone,Average,HAMT Surface Outside Face Temperature [C]
- Zone,Average,HAMT Surface Outside Face Relative Humidity [%]

#### **1.9.16.2.1 HAMT Surface Average Water Content Ratio [kg/kg]**

This output is the summed water content [kg/kg] of all cells in a surface expressed as a fraction of the mass of the water to the material mass.

#### **1.9.16.2.2 HAMT Surface Inside Face Temperature [C]**

This output is the temperature [C] on the internal “surface” of the surface.

#### **1.9.16.2.3 HAMT Surface Inside Face Relative Humidity [%]**

#### **1.9.16.2.4 HAMT Surface Inside Face Relative Humidity [%]**

This output is the relative humidity on the internal “surface” of the surface expressed as a percentage.

#### **1.9.16.2.5 HAMT Surface Inside Face Vapor Pressure [Pa]**

This output is the vapor pressure [Pa] on the internal “surface” of the surface.

#### **1.9.16.2.6 HAMT Surface Outside Face Temperature [C]**

This output is the temperature on the external “surface” of the surface.

#### **1.9.16.2.7 HAMT Surface Outside Face Relative Humidity [%]**

This output is the relative humidity on the external “surface” of the surface.

### **1.9.16.3 Internal Cell Outputs**

Detailed profile data for the variables Temperature [C], Relative Humidity [%] and Water Content [kg/kg] within each surface can also be reported. To calculate the heat and moisture transfer through surfaces HAMT splits up surfaces into discrete cells. Each cell is composed of a single material and has a position within the surface. HAMT automatically assigns cells to construction objects so that there are more cells closer to boundaries between materials and also at the “surfaces” of the surface. It is not possible for users to define their own cells.

Each surface is made from a particular construction. The construction-surface relationship is output by HAMT to the eplusout.eio file with the following format. The output also contains the HAMT cell origins and cell number for each surface combination. The coordinate system origin is defined as the exterior surface of the construction.

```
! <HAMT cells>, Surface Name, Construction Name, Cell Numbers
! <HAMT origins>, Surface Name, Construction Name, Cell origins (m)
HAMT cells, FLOOR,FLOOR, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16,
17
HAMT origins,FLOOR,FLOOR, 0.0000000, 0.0122726, 0.0601616, 0.1512518, 0.2766268, 0.4240140, 0.5789860,
0.7263732, 0.8517482, 0.9428384, 0.9907274, 1.0035729, 1.0056459, 1.0090000, 1.0123541, 1.0144271,
1.0150000
```

Users can select any one of the Temperature, Relative Humidity or Water Content variables for any cell to be reported, using the following naming scheme for the output variable.

- Zone,Average,HAMT Surface Temperature Cell N [C]
- Zone,Average,HAMT Surface Water Content Cell N [kg/kg]
- Zone,Average,HAMT Surface Relative Humidity Cell N [%]

#### **1.9.16.3.1 HAMT Surface Relative Humidity Cell <N> [%]**

This is the relative humidity of the cell in the surface.

#### **1.9.16.3.2 HAMT Surface Temperature Cell <N> [C]**

This is the temperature of the cell in the surface.

#### **1.9.16.3.3 HAMT Surface Water Content Cell <N> [kg/kg]**

This is the relative water content of the cell in the surface.

### **1.9.17 Materials for Glass Windows and Doors**

All the materials for glass windows and doors have the prefix “WindowMaterial”. The following WindowMaterial descriptions (Glazing, Glazing:RefractionExtinctionMethod, Gas, GasMixture, Shade, Screen and Blind) apply to glass windows and doors. The property definitions described herein for Glazing, Gas and GasMixture are supported by the National Fenestration Rating Council as standard.

“Front side” is the side of the layer opposite the zone in which the window is defined. “Back side” is the side closest to the zone in which the window is defined. Therefore, for exterior windows, “front side” is the side closest to the outdoors. For interior windows, “front side” is the side closest to the zone adjacent to the zone in which the window is defined.

The solar radiation transmitted by the window layers enters the zone and is a component of the zone load. The solar radiation absorbed in each solid layer (glass, shade, screen or blind) participates in the window layer heat balance calculation. The visible transmittance and reflectance properties of the window are used in the daylighting calculation.

### **1.9.18 WindowMaterial:Glazing**

In the following, for exterior windows, “front side” is the side of the glass closest to the outside air and “back side” is the side closest to the zone the window is defined in. For interzone windows, “front side” is the side closest to the zone adjacent to the zone the window is defined in and “back side” is the side closest to the zone the window is defined in.

#### **1.9.18.1 Inputs**

##### **1.9.18.1.1 Field: Name**

The name of the glass layer. It corresponds to a layer in a window construction.

#### 1.9.18.1.2 Field: Optical Data Type

Valid values for this field are SpectralAverage, Spectral, SpectralAndAngle, and BSDF.

If Optical Data Type = SpectralAverage, the values you enter for solar transmittance and reflectance are assumed to be averaged over the solar spectrum, and the values you enter for visible transmittance and reflectance are assumed to be averaged over the solar spectrum and weighted by the response of the human eye. There is an EnergyPlus Reference Data Set for WindowMaterial:Glazing that contains spectral average properties for many different types of glass.

If Optical Data Type = Spectral, then, in the following field, you must enter the name of a spectral data set defined with the WindowGlassSpectralData object. In this case, the values of solar and visible transmittance and reflectance in the fields below should be blank.

If Optical Data Type = SpectralAndAngle, then, in the last 3 fields, you must enter the name of a spectral and angle data set defined with a curve or table object with two independent variables. In this case, the Window Glass Spectral Data Set Name should be blank, and the values of solar and visible transmittance and reflectance in the fields below should be blank.

If Optical Data Type = BSDF, the [Construction:ComplexFenestrationState](#) object must be used to define the window construction layers. The [Construction:ComplexFenestrationState](#) object contains references to the BSDF files which contain the optical properties of the Complex Fenestration layers. In this case,

#### 1.9.18.1.3 Field: Window Glass Spectral Data Set Name

If Optical Data Type = Spectral, this is the name of a spectral data set defined with a WindowGlassSpectralData object.

#### 1.9.18.1.4 Field: Thickness

The surface-to-surface thickness of the glass (m).

#### 1.9.18.1.5 Field: Solar Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, solar index of refraction, and solar extinction coefficient—they can be converted to equivalent solar transmittance and reflectance values using the equations given in “[Glass Optical Properties Conversion](#).”

#### 1.9.18.1.6 Field: Front Side Solar Reflectance at Normal Incidence

Front-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

#### 1.9.18.1.7 Field: Back Side Solar Reflectance at Normal Incidence

Back-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

#### 1.9.18.1.8 Field: Visible Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, visible index of refraction, and visible extinction coefficient—they can be converted to equivalent visible transmittance and reflectance values using the equations given in “**Glass Optical Properties Conversion.**”

#### **1.9.18.1.9 Field: Front Side Visible Reflectance at Normal Incidence**

Front-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

#### **1.9.18.1.10 Field: Back Side Visible Reflectance at Normal Incidence**

Back-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

#### **1.9.18.1.11 Field: Infrared Transmittance at Normal Incidence**

Long-wave transmittance at normal incidence.

#### **1.9.18.1.12 Field: Front Side Infrared Hemispherical Emissivity**

Front-side long-wave emissivity.

#### **1.9.18.1.13 Field: Back Side Infrared Hemispherical Emissivity**

Back-side long-wave emissivity.

#### **1.9.18.1.14 Field: Conductivity**

Thermal conductivity (W/m-K).

#### **1.9.18.1.15 Field: Dirt Correction Factor for Solar and Visible Transmittance**

This is a factor that corrects for the presence of dirt on the glass. The program multiplies the fields “Solar Transmittance at Normal Incidence” and “Visible Transmittance at Normal Incidence” by this factor if the material is used as the outer glass layer of an exterior window or glass door.<sup>1</sup> If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor < 1.0 in the construction for an interior window will result in an error message.

Representative values of the dirt correction factor are shown in Table 1.13.

Table 1.13: Dirt Correction Factors

Type of Location	Angle of Glazing		
	Vertical	45°	Horizontal
Non-industrial	0.9	0.8	0.7
Industrial	0.7	0.6	0.5

<sup>1</sup>If Optical Data Type = Spectral, the program multiplies the solar and visible transmittance at each wavelength by the dirt correction factor.

Table 1.13: Dirt Correction Factors

Type of Location	Angle of Glazing		
	Vertical	45°	Horizontal
Very Dirty	0.6	0.5	0.4

From Appendix A, “Daylighting in Sports Halls, Report 2,” SportScotland, Nov. 2002 ([www.sportscotland.org.uk](http://www.sportscotland.org.uk))

The default value of the dirt correction factor is 1.0, which means the glass is clean. It is assumed that dirt, if present, has no effect on the IR properties of the glass.

#### 1.9.18.1.16 Field: Solar Diffusing

Takes values No (the default) and Yes. If No, the glass is transparent and beam solar radiation incident on the glass is transmitted as beam radiation with no diffuse component. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component.<sup>2</sup> See Figure 1.12. Solar Diffusing = Yes should only be used on the *innermost* pane of glass in an exterior window; it does not apply to interior windows.

For both Solar Diffusing = No and Yes, beam is reflected as beam with no diffuse component (see Figure 1.12). Solar Diffusing cannot be used with Window Shading Control devices (except Switchable Glazing). When attempted, the window property will be set to No for Solar Diffusing. The Surface Details report will reflect the override.

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing—which is often used in skylights—will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

#### 1.9.18.1.17 Field: Young's modulus

A measure of the stiffness of an elastic material. It is defined as the ratio of the uniaxial stress over the uniaxial strain in the range of stress in which Hooke’s Law holds. It is used only with complex fenestration systems defined through the **Construction:ComplexFenestrationState** object. The default value for glass is 7.2e10 Pa.

#### 1.9.18.1.18 Field: Poisson’s ratio

The ratio, when a sample object is stretched, of the contraction or transverse strain (perpendicular to the applied load), to the extension or axial strain (in the direction of the applied load). This value is used only with complex fenestration systems defined through the **Construction:ComplexFenestrationState** object. The default value for glass is 0.22.

<sup>2</sup>EnergyPlus does not model the “partially translucent” case in which beam solar radiation incident on the glass is transmitted as a combination of beam and diffuse.

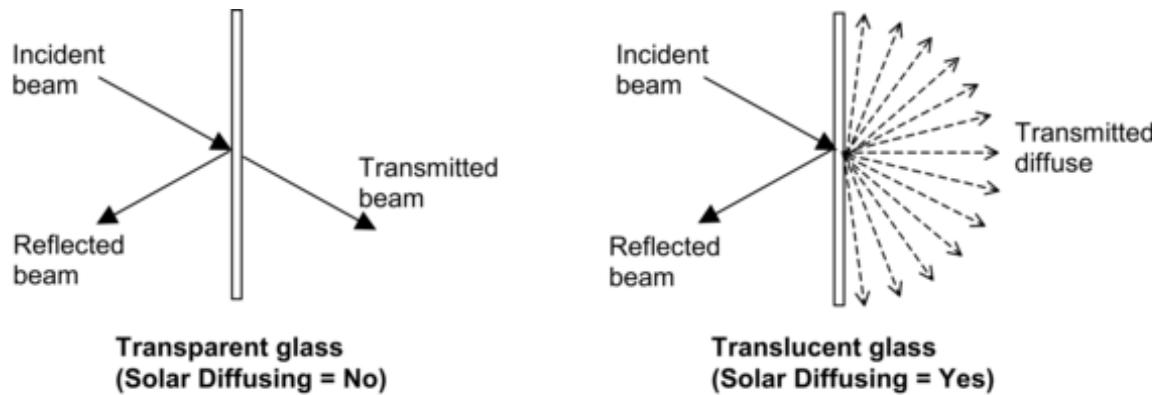

Figure 1.12: Comparison between transmittance properties of transparent glass (Solar Diffusing = No) and translucent glass (Solar Diffusing = Yes).

#### 1.9.18.1.19 Field: Window Glass Spectral and Incident Angle Transmittance Data Set Table Name

If Optical Data Type = SpectralAndAngle, this is the name of a spectral and angle data set of transmittance defined with a curve or table object with two independent variables. The first and second independent variables must be Angle, and Wavelength, respectively. The restriction is based on internal dataset use. Each dataset is divided into subsets for each incident angle internally.

#### 1.9.18.1.20 Field: Window Glass Spectral and Incident Angle Front Reflectance Data Set Table Name

If Optical Data Type = SpectralAndAngle, this is the name of a spectral and angle data set of front reflectance defined with a curve or table object with two independent variables. The first and second independent variables must be Angle, and Wavelength, respectively. The restriction is based on internal dataset use. Each dataset is divided into subsets for each incident angle internally.

#### 1.9.18.1.21 Field: Window Glass Spectral and Incident Angle Back Reflectance Data Set Table Name

If Optical Data Type = SpectralAndAngle, this is the name of a spectral and angle data set of back reflectance defined with a curve or table object with two independent variables. The first and second independent variables must be Angle, and Wavelength, respectively. The restriction is based on internal dataset use. Each dataset is divided into subsets for each incident angle internally.

It should be pointed out that when Optical Data Type = SpectralAndAngle for a glass layer in a construction, the table input data are converted into polynomial curve fits with 6 coefficients, so that all outputs of optical properties for the same construction will be curve values for a given incident angle. Therefore, the values may be slightly different from input values.

## 1.9.19 WindowMaterial:Glazing:RefractionExtinctionMethod

This is an alternative way of specifying glass properties. Index of refraction and extinction coefficient are given instead of the transmittance and reflectance values used in [WindowMaterial:Glazing](#). However, unlike [WindowMaterial:Glazing](#), [WindowMaterial:Glazing:RefractionExtinctionMethod](#) is restricted to cases where the front and back optical properties of the glass are the same. This means it cannot be used for glass with a coating on one side. In that case [WindowMaterial:Glazing](#) should be used. Also, unlike [WindowMaterial:Glazing](#), [WindowMaterial:Glazing:RefractionExtinctionMethod](#) does not allow input of glass wavelength-by-wavelength (spectral) properties.

### 1.9.19.1 Inputs

#### 1.9.19.1.1 Field: Name

The name of the glass layer. It corresponds to a layer in a window construction.

#### 1.9.19.1.2 Field: Thickness

The surface-to-surface thickness of the glass (m).

#### 1.9.19.1.3 Field: Solar Index of Refraction

Index of refraction averaged over the solar spectrum.

#### 1.9.19.1.4 Field: Solar Extinction Coefficient

Extinction coefficient averaged over the solar spectrum ( $\text{m}^{-1}$ ).

#### 1.9.19.1.5 Field: Visible Index of Refraction

Index of refraction averaged over the solar spectrum and weighted by the response of the human eye.

#### 1.9.19.1.6 Field: Visible Extinction Coefficient

Extinction coefficient averaged over the solar spectrum and weighted by the response of the human eye ( $\text{m}^{-1}$ ).

#### 1.9.19.1.7 Field: Infrared Transmittance at Normal Incidence

Long-wave transmittance at normal incidence.

#### 1.9.19.1.8 Field: Infrared Hemispherical Emissivity

Long-wave hemispherical emissivity, assumed the same on both sides of the glass.

### 1.9.19.1.9 Field: Conductivity

Thermal conductivity (W/m-K).

### 1.9.19.1.10 Field: Dirt Correction Factor for Solar and Visible Transmittance

This is a factor that corrects for the presence of dirt on the glass. It multiplies the solar and visible transmittance at normal Incidence (which the program calculates from the input values of thickness, solar index of refraction, solar extinction coefficient, etc.) if the material is used as the outer glass layer of an exterior window or glass door. If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor < 1.0 in the construction for an interior window will result in an error message.

Representative values of the direct correction factor are shown in Table 1.13.

The default value of the dirt correction factor is 1.0, which means the glass is clean. It is assumed that dirt, if present, has no effect on the IR properties of the glass.

### 1.9.19.1.11 Field: Solar Diffusing

Takes values No (the default) and Yes. If No, the glass is transparent. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component. (EnergyPlus does not model the “partially translucent” case in which beam solar radiation incident on the glass is transmitted as a combination of beam and diffuse.) Solar Diffusing = Yes should only be used on the innermost pane of glass in an exterior window; it does not apply to interior windows.

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing, which is often used in skylights, will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

An IDF example:

```
WindowMaterial:Glazing:RefractionExtinctionMethod,
4MM CLEAR GLASS,    !- Material name
0.004,              !- Thickness {m}
1.526,              !- Solar index of refraction
30.0 ,              !- Solar extinction coefficient (1/m)
1.526,              !- Visible index of refraction
30.0 ,              !- Visible extinction coefficient (1/m)
0.0,                !- IR transmittance at normal incidence
0.84,              !- IR emissivity
0.9;                !- Conductivity {W/m-K}
```

### 1.9.20 Glass Optical Properties Conversion

#### 1.9.20.1 Conversion from Glass Optical Properties Specified as Index of Refraction and Transmittance at Normal Incidence

The optical properties of uncoated glass are sometimes specified by index of refraction,  $n$ , and transmittance at normal incidence,  $T$ .

The following equations show how to convert from this set of values to the transmittance and reflectance values required by **WindowMaterial:Glazing**. These equations apply only to uncoated glass, and can be used to convert either spectral-average solar properties or spectral-average visible properties (in general,  $n$  and  $T$  are different for the solar and visible). Note that since the glass is uncoated, the front and back reflectances are the same and equal to the  $R$  that is solved for in the following equations.

Given  $n$  and  $T$ , find  $R$ :

$$r = \left( \frac{n - 1}{n + 1} \right)^2$$

$$\tau = \frac{[(1 - r)^4 + 4r^2T^2]^{1/2} - (1 - r)^2}{2r^2T}$$

$$R = r + \frac{(1 - r)^2r\tau^2}{1 - r^2\tau^2}$$

**Example:**

$$T = 0.86156$$

$$n = 1.526$$

$$r = \left( \frac{1.526 - 1}{1.526 + 1} \right)^2$$

$$\tau = 0.93974$$

$$R = 0.07846$$

### 1.9.21 WindowMaterial:GlazingGroup:Thermochromic

Thermochromic (TC) materials have active, reversible optical properties that vary with temperature. Thermochromic windows are adaptive window systems for incorporation into building envelopes. Thermochromic windows respond by absorbing sunlight and turning the sunlight energy into heat. As the thermochromic film warms it changes its light transmission level from less absorbing to more absorbing. The more sunlight it absorbs the lower the light level going through it. By using the sun's own energy the window adapts based solely on the directness and amount of sunlight. Thermochromic materials will normally reduce optical transparency by absorption and/or reflection, and are specular (maintaining vision).

A thermochromic window is defined with a Construction object which references a special layer defined with a [WindowMaterial:GlazingGroup:Thermochromic](#) object. The [WindowMaterial:GlazingGroup:Thermochromic](#) object further references a series of [WindowMaterial:Glazing](#) objects corresponding to each specification temperature of the TC layer.

This object specifies a layer of thermochromic glass, part of a thermochromic window. An example file ThermochromicWindow.idf is included in the EnergyPlus installation.

### 1.9.21.1 Inputs

#### 1.9.21.1.1 Field: Name

A unique user assigned name for a particular thermochromic glass material.

#### 1.9.21.1.2 Field Set (Optical Data Temperature, Window Material Glazing Name)

This object is extensible, so additional sets of the next two fields can be added to the end of this object.

#### 1.9.21.1.3 Field:Optical Data Temperature <N>

The temperature of the TC glass layer corresponding to the optical data of the TC layer. Unit is °C.

#### 1.9.21.1.4 Field: Window Material Glazing Name <N>

The window glazing (defined with [WindowMaterial:Glazing](#)) name that provides the TC glass layer performance at the above specified temperature.

### 1.9.21.2 Outputs

#### 1.9.21.2.1 Surface Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

#### 1.9.21.2.2 Surface Window Thermochromic Layer Property Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the EIO file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “\_TC\_XX” where XX represents a specification temperature.

### 1.9.22 WindowMaterial:Gas

This object specifies the properties of the gas between the panes of a multi-pane window. Gas Type = Custom allows you to specify the properties of gases other than air, Argon, Krypton or Xenon. There is an EnergyPlus Reference Data Set for Material:WindowGas that contains several types of gas of different thicknesses. See Material:WindowGasMixture for the case that the gas fill is a mixture of different gases.

#### 1.9.22.1 Inputs

##### 1.9.22.1.1 Field: Name

The name of the gas fill. It refers to a layer in a window construction.

##### 1.9.22.1.2 Field: Gas Type

The type of gas. The choices are Air, Argon, Krypton, or Xenon. If Gas Type = Custom you can use Conductivity Coefficient A, etc. to specify the properties of a different type of gas.

**1.9.22.1.3 Field: Thickness**

The thickness (m) of the gas layer.

**1.9.22.1.4 Properties for Custom Gas Types**

The following entries are used only if Gas Type = Custom. The A and B coefficients are those in the following expression that gives a property value as a function of temperature in degrees K:

$$\text{Property} = \text{Coefficient}_A + \text{Coefficient}_B * \text{Temperature}_K + \text{Coefficient}_C * \text{Temperature}_K^2 \quad (1.14)$$

**1.9.22.1.5 Field: Conductivity Coefficient A**

The A coefficient for gas conductivity (W/m-K). Used only if Gas Type = Custom.

**1.9.22.1.6 Field: Conductivity Coefficient B**

The B coefficient for gas conductivity (W/m-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.22.1.7 Field: Conductivity Coefficient C**

The C coefficient for gas conductivity (W/m-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.9.22.1.8 Field: Viscosity Coefficient A**

The A coefficient for gas viscosity (kg/m-s). Used only if Gas Type = Custom.

**1.9.22.1.9 Field: Viscosity Coefficient B**

The B coefficient for gas viscosity (kg/m-s-K). Used only if Gas Type = Custom.

**1.9.22.1.10 Field: Viscosity Coefficient C**

The C coefficient for gas viscosity (kg/m-s-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.22.1.11 Field: Specific Heat Coefficient A**

The A coefficient for gas specific heat (J/kg-K). Used only if Gas Type = Custom.

**1.9.22.1.12 Field: Specific Heat Coefficient B**

The B coefficient for gas specific heat (J/kg-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.22.1.13 Field: Specific Heat Coefficient C**

The C coefficient for gas specific heat (J/kg-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.9.22.1.14 Field: Specific Heat Ratio**

The specific heat ratio for gas. Used only if Gas Type = Custom.

**1.9.22.1.15 Field: Molecular Weight**

The molecular weight for gas. The molecular weight is the mass of 1 mol of the substance. This has a numerical value which is the average molecular mass of the molecules in the substance multiplied by Avogadro's constant. (kg/kmol) (Shown in the IDD as g/mol for consistency)

### 1.9.22.1.16 Field: Specific Heat Ratio

The specific heat ratio for gas. The specific heat ratio of a gas is the ratio of the specific heat at constant pressure, to the specific heat at constant volume. Used only if Gas Type = Custom.

An IDF example:

```
WindowMaterial:Gas,AIRGAP,
  AIR,          ! Gas type (Air - Argon - Krypton - Xenon - Custom)]
  0.0125;      ! Thickness {m} 1/2 inch
```

An IDF example to be used with a [WindowMaterial:Gap](#) definition (see below)

```
WindowMaterial:Gas,
  Gas_1_W_0_0100,                      !- gap name - Air
  Air,                                     !- type
  0.0100;                                  !- thickness
```

An IDF example for a Custom Gas

```
WindowMaterial:Gas,
  Gas_16_W_0_0003,                      !- gap name
  Custom,                                 !- type
  0.0003,                                !- thickness
  2.873000e-003,                         !- Conductivity Coefficient A
  7.760000e-005,                         !- Conductivity Coefficient B
  0.000000e+000,                         !- Conductivity Coefficient C
  3.723000e-006,                         !- Conductivity Viscosity A
  4.940000e-008,                         !- Conductivity Viscosity B
  0.000000e+000,                         !- Conductivity Viscosity C
  1002.737000,                           !- Specific Heat Coefficient A
  0.012324,                               !- Specific Heat Coefficient B
  0.000000,                               !- Specific Heat Coefficient C
  28.969999,                             !- Molecular Weight
  1.400000;                               !- Specific Heat Ratio
```

## 1.9.23 WindowMaterial:GasMixture

This object allows you to specify the fill between the panes of a multi-pane window to be a mixture of two, three or four different gases chosen from air, argon, krypton and xenon. It can also be used if only one type of gas in the fill. In this case you can also use [WindowMaterial:Gas](#). Note that the fractions of gas types in the mixture should add up to 1.0.

### 1.9.23.1 Inputs

#### 1.9.23.1.1 Field: Name

The name of the gas mixture. It refers to a layer in a window construction.

#### 1.9.23.1.2 Field: Thickness

The thickness (m) of the gas mixture layer.

#### 1.9.23.1.3 Field: Number of Gases in Mixture

The number of different types of gas in the mixture ( a value from 1 to 4)

#### 1.9.23.1.4 Set: Gas Type-Fraction (up to 4)

### 1.9.23.1.5 Field: Gas 1 Type

The type of the first gas in the mixture. Choices are Air, Argon, Krypton and Xenon.

### 1.9.23.1.6 Field: Gas 1 Fraction

The fraction of the first gas in the mixture.

An IDF example:

```
WindowMaterial:GasMixture,ArgonKryptonMix,
0.0125,      ! Thickness {m} 1/2 inch
2,           ! Number of Gases in Mixture
Argon,        ! Gas 1 Type
0.6,          ! Gas 1 Fraction
Krypton,       ! Gas 2 Type
0.4;          ! Gas 2 Fraction
```

## 1.9.24 WindowMaterial:Gap

This input object is used to define the gap between two layers in a complex fenestration system, where the [Construction:ComplexFenestrationState](#) object is used. It references the gas or gas mixtures defined in the [WindowMaterial:Gas](#) and [WindowMaterial:GasMixture](#) objects. It is referenced as a layer in the [Construction:ComplexFenestrationState](#) object ;it cannot be referenced as a layer from the Construction object.

### 1.9.24.1 Inputs

#### 1.9.24.1.1 Field: Name

Unique name of the gap.

#### 1.9.24.1.2 Field: Thickness

The thickness (m) of the gap layer.

#### 1.9.24.1.3 Field: Pressure

The pressure (Pa) of the gas in the gap layer, used to calculate the gas properties of the glazing system gap. Default is atmospheric pressure, 101325 Pa. When modeling vacuum glazing, this value should represent the pressure in the evacuated glazing system. If this pressure is less than the ThermalModelParams:PressureLimit value, the the glazing system will be modeled as a vacuum glazing.

#### 1.9.24.1.4 Field: Deflection State

This field is used when modeling the deflection of the glass layers in a window if the [WindowThermalModel:Params](#) value for “deflection model” is “MeasuredDeflection”.

#### 1.9.24.1.5 Field: Support Pillar

References the support pillar of the gap layer if vacuum glazing is being modeled. If left empty, then it is considered that gap layer does not have support pillars.

### 1.9.24.1.6 Field: Gas (or GasMixture)

References gas ([WindowMaterial:Gas](#)) or gas mixture ([WindowMaterial:GasMixture](#)) of the gap layer.

An IDF example for simple glazing:

```
WindowMaterial:Gas,
Gas_1_W_0_0120,
Air,
0.0120;
                                     !- gap name - Air
                                     !- type
                                     !- thickness

WindowMaterial:Gap,
Gap_1_Layer,
0.0120,
Gas_1_W_0_0120,
101325.0000;
                                     !- gap name: Air
                                     !- thickness
                                     !- Gas (or Gas Mixture) name
                                     !- pressure
```

An IDF example for vacuum glazing:

```
WindowMaterial:Gap,
Gap_16_Layer,
0.0003,
                                     !- gap name: Vacuum_0.001_pr-0.5_ps-50.8
                                     !- thicknessGas_16_W_0_0003,
                                     !- Gas (or Gas Mixture) name
0.1333,
                                     !- pressure
                                     !- deflection state
                                     !- SupportPillar
,
SupportPillar_16_Gap_1;
                                     !- SupportPillar

WindowGap:SupportPillar,
SupportPillar_16_Gap_1,
0.0508,
0.0005;
                                     !- Name
                                     !- spacing
                                     !- radius
```

## 1.9.25 WindowGap:DeflectionState

This input object is used to enter data describing deflection state of the gap. It is referenced from [WindowMaterial:Gap](#) object only and it is used only when deflection model is set to MeasuredDeflection (see [WindowThermalModel:Params](#)), otherwise it is ignored.

### 1.9.25.1 Inputs

#### 1.9.25.1.1 Field: Name

Unique name of the deflection state.

#### 1.9.25.1.2 Field: Deflected Thickness

The thickness (m) of the gap in deflected state. It represents value of deflection at point of maximum which is usually at the center poing of glazing system. It is used only with tarcog algorithm set to Measured Deflection ([WindowThermalModel:Params](#)), otherwise this field will be ignored.

An IDF example where [WindowThermalModel:Params](#) Deflection Model = MeasuredDeflection:

```
WindowMaterial:Gap,
Gap_1_Layer,
0.0120,
Gas_1_W_0_0120,
101325.0000;
                                     !- gap name: Air
                                     !- thickness
                                     !- Gas (or Gas Mixture) name
                                     !- pressure
```

```

Gap_1_Deflection;           !- deflection state

WindowGap:DeflectionState,
  Gap_1_Deflection,        !- deflection state of gap
  0.011;                  !- name
                           !- gap thickness in deflected state

```

### 1.9.26 WindowGap:SupportPillar

This input object is used to enter data describing support pillar of the gap. Support pillars are used in vacuum glazing in order to prevent deflection of glass layers.

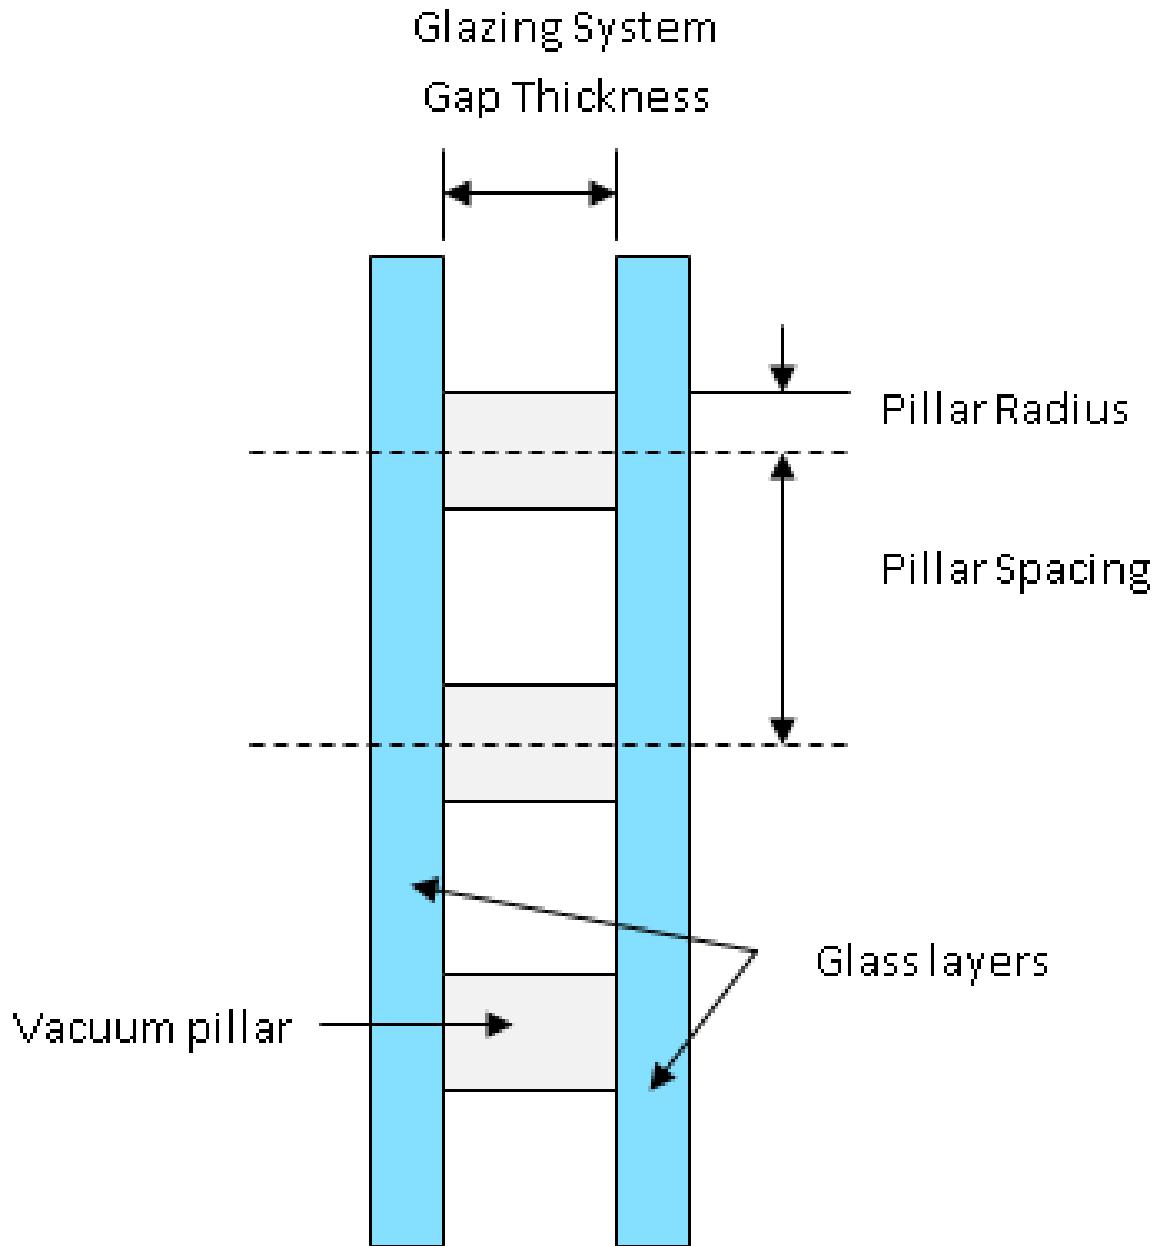

Figure 1.13: Support Pillar

### 1.9.26.1 Inputs

#### 1.9.26.1.1 Field: Name

Unique name of the support pillar.

#### 1.9.26.1.2 Field: Spacing

Distance (m) between support pillar centers (see the Engineering reference document for more information).

#### 1.9.26.1.3 Field: Radius

The radius (m) of the support pillar (see Engineering reference document for more information).

An IDF example for vacuum glazing (see Vacuum Glazing example in [WindowMaterial:Gap](#) above)

```
WindowGap:SupportPillar,      !- gap support pillar
  SupportPillar_16_Gap_1,    !- basis matrix name
  0.05,                      !- pillar spacing
  0.005;                     !- pillar radius
```

### 1.9.27 WindowMaterial:SimpleGlazingSystem

**This model should be used with caution. There may be significant differences in performance between the simple window system and the usual more detailed model.**

This input object differs from the other WindowMaterial objects in that it describes an entire glazing system rather than individual layers. This object is used when only very limited information is available on the glazing layers or when specific performance levels are being targeted. The layer by layer description offers superior method of modeling windows that should be used instead of this object when sufficient data are available. This object accesses a model that turns simple performance indices into a fuller model of the glazing system.

The performance indices are U-factor and Solar Heat Gain Coefficient, and optionally Visible Transmittance. The values for these performance indices can be selected by the user to represent either glazing-only windows (with no frame) or an average window performance that includes the frame. Inside the program the model produces an equivalent window glazing layer with no frame. The properties of the modeled glazing layer are reported to the EIO file using the IDF input object syntax for the [WindowMaterial:Glazing](#) input object. This equivalent layer could be reused in subsequent models if desired, however there will be important differences in the modeled window performance because the simple glazing system model includes its own special model for angular dependence when incident beam solar is not normal to the plane of the window.

When this object is referenced in a Construction object, it cannot be used with other glazing or gas material layers. Shades or blinds cannot be located between the glass, but these can be used on the inside or the outside of the glazing system. If the glazing system does have between-the-glass shades or blinds, then the U and SHGC values entered in this object should include the impacts of those layers. Adding window treatment layers such as shades or screens will alter the overall performance to be different than the performance levels prescribed in this object.

### 1.9.27.1 Inputs

#### 1.9.27.1.1 Field: Name

The name of the glazing system. This value is unique across all constructions.

### 1.9.27.1.2 Field: U-Factor

This field describes the value for window system U-Factor, or overall heat transfer coefficient. Units are in  $\text{W}/\text{m}^2 \cdot \text{K}$ . This is the rated (NFRC) value for U-factor under winter heating conditions. The U-factor is assumed to be for vertically mounted products. In versions up till 9.6.0, the maximum allowable input is U-7.0  $\text{W}/\text{m}^2 \cdot \text{K}$ , and the effective upper limit of the glazing generated by the underlying model is around U-5.8  $\text{W}/\text{m}^2 \cdot \text{K}$ . In later versions, such upper bound of the input U value is removed. So is the mis-match between the user input U and the effective U is resolved.

### 1.9.27.1.3 Field: Solar Heat Gain Coefficient

This field describes the value for SHGC, or solar heat gain coefficient. There are no units. This is the rated (NFRC) value for SHGC under summer cooling conditions and represents SHGC for normal incidence and vertical orientation.

### 1.9.27.1.4 Field: Visible Transmittance

This field is optional. If it is omitted, then the visible transmittance properties are taken from the solar properties. If it is included then the model includes it when developing properties for the glazing system. This is the rated (NFRC) value for visible transmittance at normal incidence.

An example of this object.

```
WindowMaterial:SimpleGlazingSystem,
  SimpleWindow:DOUBLE PANE WINDOW , !- Name
  2.716 , !- U-Factor
  0.763 , !- Solar Heat Gain Coefficient
  0.812 ; !- Visible Transmittance
```

## 1.9.28 WindowMaterial:Shade

This object specifies the properties of window shade materials. Reflectance and emissivity properties are assumed to be the same on both sides of the shade. Shades are considered to be perfect diffusers (all transmitted and reflected radiation is hemispherically-diffuse) with transmittance and reflectance independent of angle of incidence. There is an EnergyPlus Reference Data Set for WindowMaterial:Shade that contains properties of generic window shades.

Window shades can be on the inside of the window (“interior shades”), on the outside of the window (“exterior shades”), or between glass layers (“between-glass shades”). When in place, the shade is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the shade is assumed to be parallel to the glazing.

WindowMaterial:Shade can be used for diffusing materials such as drapery and translucent roller shades. For slat-type shading devices, like Venetian blinds, that have a strong angular dependence of transmission, absorption and reflection, it is better to use [WindowMaterial:Blind](#). [WindowMaterial:Screen](#) should be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation.

Transmittance and reflectance values for drapery material with different color and openness of weave can be obtained from manufacturers or determined from 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31.

There are two methods of assigning a shade to a window:

### 1.9.28.1 Inputs

#### 1.9.28.1.1 Method 1:

- 1) Define the construction of the window without the shade, the so-called “bare” construction.

- 2) Reference the bare construction in the **FenestrationSurface:Detailed** for the window.
- 3) Define the **WindowMaterial:Shade**.
- 4) Define a **WindowShadingControl** for the window in which you (a) specify that this **WindowMaterial:Shade** is the window's shading device and (b) specify how the shade is controlled.

#### **1.9.28.1.2 Method 2:**

- 1) Define the Construction of the window without the shade, the so-called “bare” construction.
- 2) Reference the bare construction in the **FenestrationSurface:Detailed** for the window.
- 3) Define the **WindowMaterial:Shade**.
- 4) Define another Construction, called the “shaded construction,” that includes the **WindowMaterial:Shade**.
- 5) Define a **WindowShadingControl** for the window in which you (a) reference the shaded construction and (b) specify how the shade is controlled.

Note that **WindowShadingControl** has to be used with either method, even if the shade is in place at all times. You will get an error message if you try to reference a shaded construction directly from **FenestrationSurface:Detailed**.

#### **1.9.28.1.3 Field: Name**

Name of the shade. It is referenced as an inside or outside layer in a window construction.

#### **1.9.28.1.4 Field: Solar Transmittance**

Transmittance averaged over the solar spectrum. Assumed independent of incidence angle.

#### **1.9.28.1.5 Field: Solar Reflectance**

Reflectance averaged over the solar spectrum. Assumed same on both sides of shade and independent of incidence angle.

#### **1.9.28.1.6 Field: Visible Transmittance**

Transmittance averaged over the solar spectrum and weighted by the response of the human eye. Assumed independent of incidence angle.

#### **1.9.28.1.7 Field: Visible Reflectance**

Reflectance averaged over the solar spectrum and weighted by the response of the human eye. Assumed same on both side of shade and independent of incidence angle.

#### **1.9.28.1.8 Field: Infrared Hemispherical Emissivity**

Effective long-wave emissivity. Assumed same on both sides of shade. We can approximate this effective emissivity,  $\varepsilon_{eff}$ , as follows. Let  $\eta$  be the “openness” the shade, i.e., the ratio of the area of openings in the shade to the overall shade area (see Field: Air-Flow Permeability, below). Let the emissivity of the shade material be  $\varepsilon$ . Then

$$\varepsilon_{eff} \approx \varepsilon (1 - \eta) \quad (1.15)$$

For most non-metallic materials  $\varepsilon$  is about 0.9.

### 1.9.28.1.9 Field: Infrared Transmittance

Effective long-wave transmittance. Assumed independent of incidence angle. We can approximate this effective long-wave transmittance,  $T_{\text{eff}}$  as follows. Let  $\eta$  be the “openness” of the shade, i.e., the ratio of the area of openings in the shade to the overall shade area. Let the long-wave transmittance of the shade material be  $T$ . Then

$$T_{\text{eff}} \approx \eta + T(1 - \eta) \quad (1.16)$$

For most materials  $T$  is very close to zero, which gives

$$T_{\text{eff}} \approx \eta \quad (1.17)$$

### 1.9.28.1.10 Field: Thickness

Thickness of the shade material (m). If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average thickness normal to the plane of the shade should be used.

### 1.9.28.1.11 Field: Conductivity

Shade material conductivity (W/m-K).

### 1.9.28.1.12 Field: Shade to Glass Distance

Distance from shade to adjacent glass (m). This is denoted by  $s$  in Figure 1.14 and Figure 1.15, below. If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average shade-to-glass distance should be used. (The shade-to-glass distance is used in calculating the natural convective air flow between glass and shade produced by buoyancy effects.). Not used for between-glass shades.

In the following,  $H$  is the glazing height and  $W$  is the glazing width.

### 1.9.28.1.13 Field: Top Opening Multiplier

Effective area for air flow at the top of the shade divided by  $sW$ , the horizontal area between glass and shade (see Figures below).

### 1.9.28.1.14 Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the shade divided by  $sW$ , the horizontal area between glass and shade (see Figures below).

### 1.9.28.1.15 Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the shade divided by  $sH$ , the vertical area between glass and shade (see Figures below).

### 1.9.28.1.16 Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the shade divided by  $sH$ , the vertical area between glass and shade (see Figures below).

### 1.9.28.1.17 Field: Air-Flow Permeability

The fraction of the shade surface that is open to air flow, i.e., the total area of openings (“holes”) in the shade surface divided by the shade area,  $HW$ . If air cannot pass through the shade material, Air-Flow Permeability = 0. For drapery fabric and screens the Air-Flow Permeability can be taken as the “openness” of the fabric (see 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31), which is 0.0 to 0.07 for closed weave, 0.07 to 0.25 for semi-open weave, and 0.25 and higher for open weave.

An IDF example:

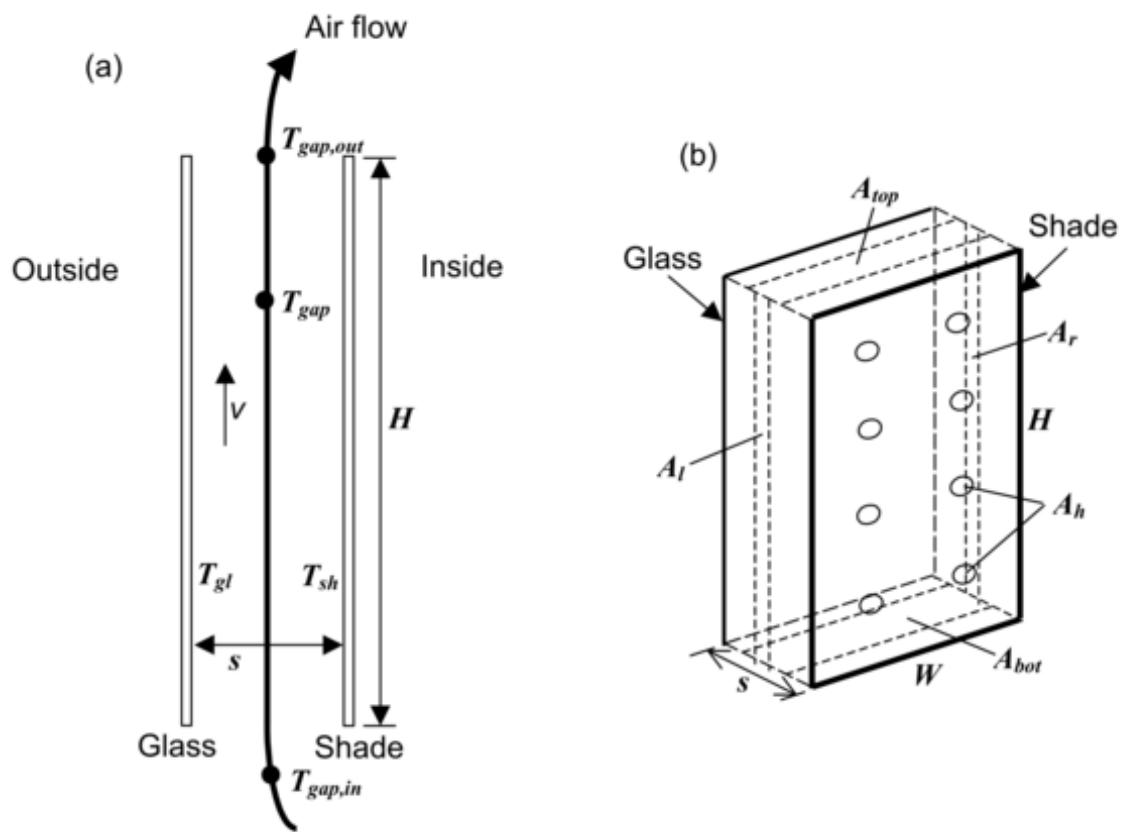

Figure 1.14: Vertical section (a) and perspective view (b) of glass and interior shade layers showing variables used in the gap air flow analysis. In (b), the air-flow opening areas  $A_{bot}$ ,  $A_{top}$ ,  $A_l$ ,  $A_r$  and  $A_h$  are shown schematically. See *Engineering Manual* for definition of thermal variables.

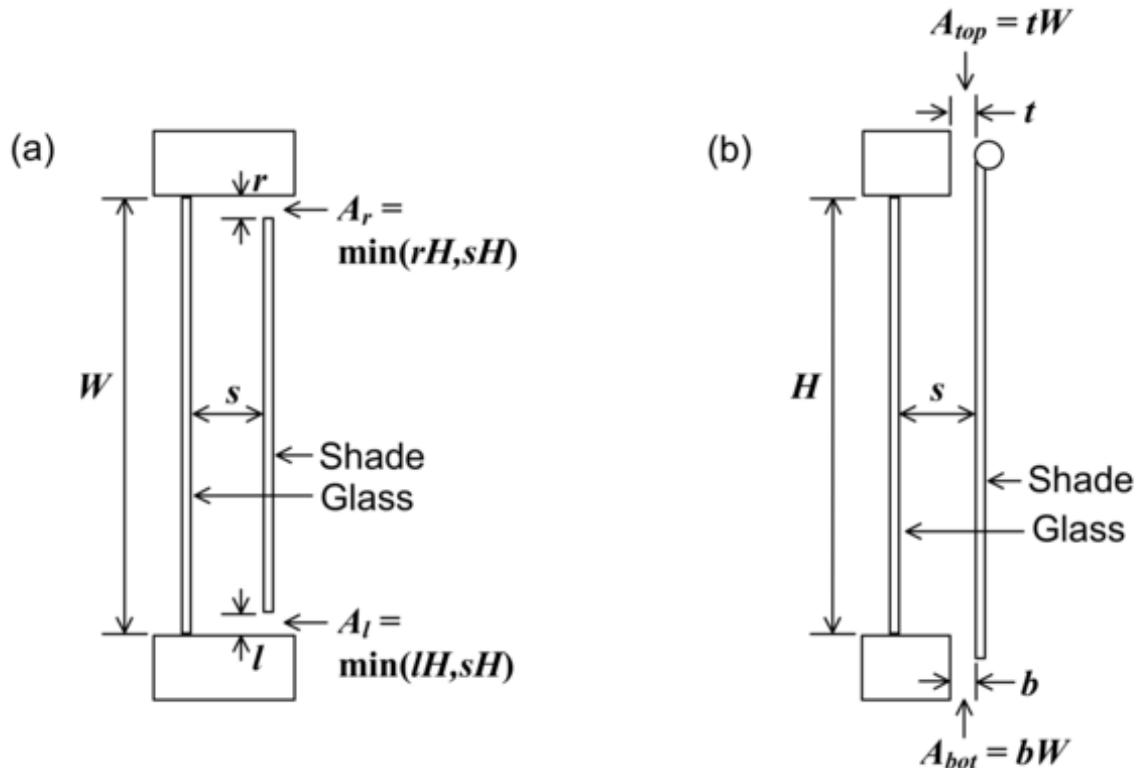

Figure 1.15: Examples of air-flow openings for an interior shade covering glass of height  $H$  and width  $W$ . Not to scale. (a) Horizontal section through shade with openings on the left and right sides (top view). (b) Vertical section through shade with openings at the top and bottom (side view). In (a) Left-Side Opening Multiplier =  $A_l/sH = \min(l/s, 1)$  and Right-Side Opening Multiplier =  $A_r/sH = \min(r/s, 1)$ . In (b) Top Opening Multiplier =  $A_{top}/sW = t/s$  and Bottom Opening Multiplier =  $A_{bot}/sW = b/s$ .

```

## 1.9.29 WindowMaterial:Blind

This object specifies the properties of a window blind consisting of flat, equally-spaced slats. Unlike window shades, which are modeled as perfect diffusers, window blinds have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation. There is an EnergyPlus Reference Data Set for WindowMaterial:Blind that contains properties of generic window blinds.

Blinds can be located on the inside of the window (“interior blinds”), on the outside of the window (“exterior blinds”), or between two layers of glass (“between-glass blinds”). When in place, the blind is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the blind is assumed to be parallel to the glazing. When the blind is retracted it is assumed to cover none of the window. The solar and thermal effects of the blind’s support strings, tapes or rods are ignored. Slat curvature, if present, is ignored.

There are two methods of assigning a blind to a window:

### 1.9.29.1 Inputs

#### 1.9.29.1.1 Method 1:

- 1) Define the construction of the window without the blind, the so-called “bare” construction.
- 2) Reference the bare construction in the [FenestrationSurface:Detailed](#) for the window.
- 3) Define the WindowMaterial:Blind.
- 4) Define a [WindowShadingControl](#) for the window in which you (a) specify that this WindowMaterial:Blind is the window’s shading device and (b) specify how the blind is controlled.

#### 1.9.29.1.2 Method 2:

- 1) Define the Construction of the window without the blind, the so-called “bare” construction.
- 2) Reference the bare construction in the [FenestrationSurface:Detailed](#) for the window.
- 3) Define the WindowMaterial:Blind.
- 4) Define another Construction, called the “shaded construction,” that includes the WindowMaterial:Blind.
- 5) Define a [WindowShadingControl](#) for the window in which you (a) reference the shaded construction and (b) specify how the blind is controlled.

Note that [WindowShadingControl](#) has to be used with either method, even if the blind is in place at all times. You will get an error message if you try to reference a construction with a blind directly from Window objects ([FenestrationSurface:Detailed](#) or [Window](#)).

Note also that [WindowShadingControl](#) is used to determine not only when the blind is in place, but how its slat angle is controlled.

### 1.9.29.1.3 Field: Name

Name of the blind. It is referenced as a layer in a window construction (ref: Construction object) or as a “Material Name of Shading Device” in a **WindowShadingControl** object.

### 1.9.29.1.4 Field: Slat Orientation

The choices are Horizontal and Vertical. “Horizontal” means the slats are parallel to the bottom of the window; this is the same as saying that the slats are parallel to the X-axis of the window. “Vertical” means the slats are parallel to Y-axis of the window.

### 1.9.29.1.5 Field: Slat Width

The width of the slat measured from edge to edge (m). See Figure 1.16.

### 1.9.29.1.6 Field: Slat Separation

The distance between the front of a slat and the back of the adjacent slat (m). See Figure 1.16.

### 1.9.29.1.7 Field: Slat Thickness

The distance between the faces of a slat (m). See Figure 1.16.

### 1.9.29.1.8 Field: Slat Angle

The angle (degrees) between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat (degrees). See Figure 1.16.

If the **WindowShadingControl** for the blind has Type of Slat Angle Control for Blinds = FixedSlatAngle, the slat angle is fixed at “Slat Angle.”

If Type of Slat Angle Control for Blinds = BlockBeamSolar, the program automatically adjusts the slat angle so as just block beam solar radiation. In this case the value of “Slat Angle” is used only when the blind is in place and there is no beam solar radiation incident on the blind.

If Type of Slat Angle Control for Blinds = ScheduledSlatAngle, the slat angle is variable. In this case “Slat Angle” is not applicable and the field should be blank.

If Type of Slat Angle Control for Blinds = FixedSlatAngle and “Slat Angle” is less than the minimum or greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, the slat angle will be reset to the corresponding minimum or maximum and a warning will be issued.

### 1.9.29.1.9 Field: Slat Conductivity

The thermal conductivity of the slat (W/m-K).

### 1.9.29.1.10 Field: Slat Beam Solar Transmittance

The beam solar transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent).

### 1.9.29.1.11 Field: Front Side Slat Beam Solar Reflectance

The beam solar reflectance of the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

### 1.9.29.1.12 Field: Back Side Slat Beam Solar Reflectance

The beam solar reflectance of the back side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.9.29.1.13 Field: Slat Diffuse Solar Transmittance**

The slat transmittance for hemispherically diffuse solar radiation. This value should equal “Slat Beam Solar Transmittance.”

**1.9.29.1.14 Field: Front Side Slat Diffuse Solar Reflectance**

The front-side slat reflectance for hemispherically diffuse solar radiation. This value should equal “Front Side Slat Beam Solar Reflectance.”

**1.9.29.1.15 Field: Back Side Slat Diffuse Solar Reflectance**

The back-side slat reflectance for hemispherically diffuse solar radiation. This value should equal “Back Side Slat Beam Solar Reflectance.”

**1.9.29.1.16 Field: Slat Beam Visible Transmittance**

The beam visible transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted visible radiation is assumed to be 100% diffuse (i.e., slats are translucent).

**1.9.29.1.17 Field: Front Side Slat Beam Visible Reflectance**

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.9.29.1.18 Field: Back Side Slat Beam Visible Reflectance**

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.9.29.1.19 Field: Slat Diffuse Visible Transmittance**

The slat transmittance for hemispherically diffuse visible radiation. This value should equal “Slat Beam Visible Transmittance.”

**1.9.29.1.20 Field: Front Side Slat Diffuse Visible Reflectance**

The front-side slat reflectance for hemispherically diffuse visible radiation. This value should equal “Front Side Slat Beam Visible Reflectance.”

**1.9.29.1.21 Field: Back Side Slat Diffuse Visible Reflectance**

The back-side slat reflectance for hemispherically diffuse visible radiation. This value should equal “Back Side Slat Beam Visible Reflectance..”

**1.9.29.1.22 Field: Slat Infrared Hemispherical Transmittance**

The slat Infrared transmittance. It is zero for solid metallic, wooden or glass slats, but may be non-zero in some cases (e.g., thin plastic slats).

**1.9.29.1.23 Field: Front Side Slat Infrared Hemispherical Emissivity**

Front-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished with a metallic paint.

#### 1.9.29.1.24 Field: Back Side Slat Infrared Hemispherical Emissivity

Back-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished with a metallic paint.

#### 1.9.29.1.25 Field: Blind to Glass Distance

For interior and exterior blinds, the distance from the mid-plane of the blind to the adjacent glass (m). See Figure 1.16. Not used for between-glass blinds. As for window shades (ref: [WindowMaterial:Shade](#)) this distance is used in calculating the natural convective air flow between glass and blind that is produced by buoyancy effects.

#### 1.9.29.1.26 Opening Multipliers

The following opening multipliers are defined in the same way as for window shades (see [WindowMaterial:Shade](#), Figure 1.14 and Figure 1.15). Note that, unlike window shades, there is no input for Air-Flow Permeability; this is automatically calculated by the program from slat angle, width and separation.

#### 1.9.29.1.27 Field: Blind Top Opening Multiplier

Defined as for Material:WindowShade.

#### 1.9.29.1.28 Field: Blind Bottom Opening Multiplier

Defined as for Material:WindowShade.

#### 1.9.29.1.29 Field: Blind Left-Side Opening Multiplier

Defined as for Material:WindowShade.

#### 1.9.29.1.30 Field: Blind Right-Side Opening Multiplier

Defined as for Material:WindowShade.

#### 1.9.29.1.31 Field: Minimum Slat Angle

The minimum allowed slat angle (degrees). Used only if [WindowShadingControl](#) (for the window that incorporates this blind) varies the slat angle (i.e., the [WindowShadingControl](#) has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle less than Minimum Slat Angle it will be reset to Minimum Slat Angle. (Note that if the Minimum Slat Angle itself is less than the minimum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that minimum.)

#### 1.9.29.1.32 Field: Maximum Slat Angle

The maximum allowed slat angle (degrees). Used only if [WindowShadingControl](#) (for the window that incorporates this blind) varies the slat angle (i.e., the [WindowShadingControl](#) has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle greater than Maximum Slat Angle the slat angle will be reset to Maximum Slat Angle. (Note that if the Maximum Slat Angle itself is greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that maximum.)

## 1.9.30 WindowMaterial:ComplexShade

This input object is used to define shade layers used in the [Construction:ComplexFenestrationState](#) object.

### 1.9.30.1 Inputs

#### 1.9.30.1.1 Field: Name

Unique name of the shading layer.

#### 1.9.30.1.2 Field: Shading Layer Type

The type of shading layer. The options are:

- VenetianHorizontal – for modeling horizontal venetian blinds
- VenetianVertical – for modeling vertical venetian blinds
- Woven – for modeling shading systems with a regular weave
- Perforated – for modeling perforated screens
- BSDF – for modeling shades whose properties are represented by a BSDF file
- OtherShadingType – for modeling shading systems which do not belong to the any of the previous group

#### 1.9.30.1.3 Field: Thickness

The thickness (m) of the shading layer. This value is ignored for ShadingLayerType = Venetian\*, because the program will calculate the thickness based on the slat angle. This value is needed for ShadingLayerType = Woven and Perforated

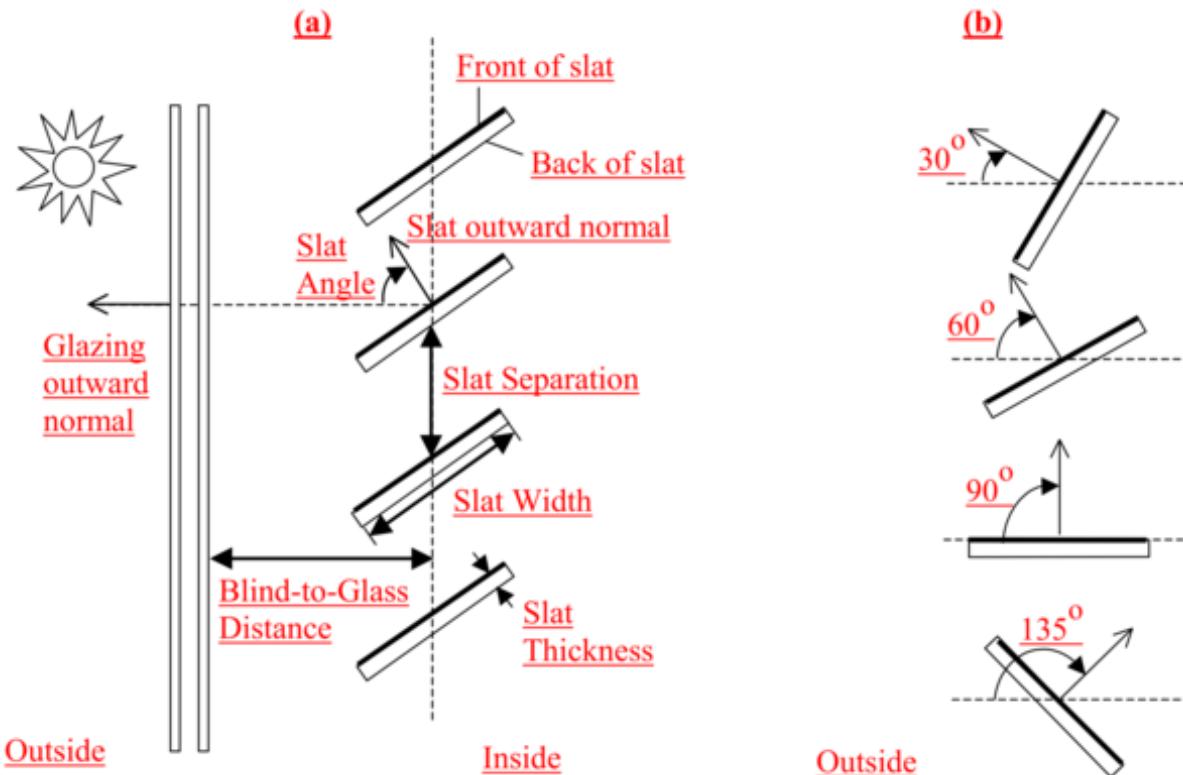

Figure 1.16: (a) Side view of a window blind with horizontal slats (or top view of blind with vertical slats) showing slat geometry. The front face of a slat is shown by a heavy line. The slat angle is defined as the angle between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat. (b) Slat orientations for representative slat angles. The slat angle varies from  $0^\circ$ , when the front of the slat is parallel to the glazing and faces toward the outdoors, to  $90^\circ$ , when the slat is perpendicular to the glazing, to  $180^\circ$ , when the front of the slat is parallel to the glazing and faces toward the indoors. The minimum and maximum slat angles are determined by the slat thickness, width and separation.

#### 1.9.30.1.4 Field: Conductivity

The conductivity (W/mK) of the shading layer material. Default: 1.0

- Venetian\* – the conductivity of the venetian blind slat material
- Woven – the conductivity of the woven shade material (such as the thread for a fabric shade)
- Perforated – for modeling perforated screens
- BSDF – for modeling shades whose properties are represented by a BSDF file
- OtherShadingType – for modeling shading systems which do not belong to the any of the previous group

#### 1.9.30.1.5 Field: IR Transmittance

The IR transmittance of the shading layer. Minimum value: 0. Maximum value: 1. Default: 0.

#### 1.9.30.1.6 Field: Front Emissivity

The front emissivity of the shading layer. Minimum value: > 0. Maximum value: 1. Default: 0.90.

#### 1.9.30.1.7 Field: Back Emissivity

The back emissivity of the shading layer. Minimum value: > 0. Maximum value: 1. Default: 0.90.

#### 1.9.30.1.8 Field: Top Opening Multiplier

The top opening multiplier value will depend on the location of the shading device within the glazing system. There are several possible scenarios which can occur and they can be divided into two groups:

##### Shading device on the indoor/outdoor side of the window

In this case the opening multiplier is calculated as the smallest distance between the shading device and the frame ( $d_{top}$ ), divided by the gap width (S). There are three possible cases for the position of a shading device the on indoor/outdoor side (see Figure 1.17).

In the case where the distance between the frame and the shading device is bigger than the gap width, the  $d_{top}$  multiplier is equal to one. Therefore, the calculation of the  $D_{top}$  opening multiplier is:

$$A_{top} = \min(d_{top}/S, 1)$$

##### Shading device between glass layers

In this case the opening multiplier is calculated as the smallest distance between the shading device and the frame or spacer ( $d_{top}$ ), divided by the smaller gap width (the minimum of (S<sub>1</sub> and S<sub>2</sub>)).

The  $D_{top}$  opening multiplier for a between glass shade is calculated as:

$$A_{top} = \min(d_{top}/S_{min}, 1)$$

Where

$$S_{min} = \min(S_1, S_2)$$

#### 1.9.30.1.9 Field: Bottom Opening Multiplier

The bottom opening multiplier ( $d_{bot}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the bottom of the shading device.

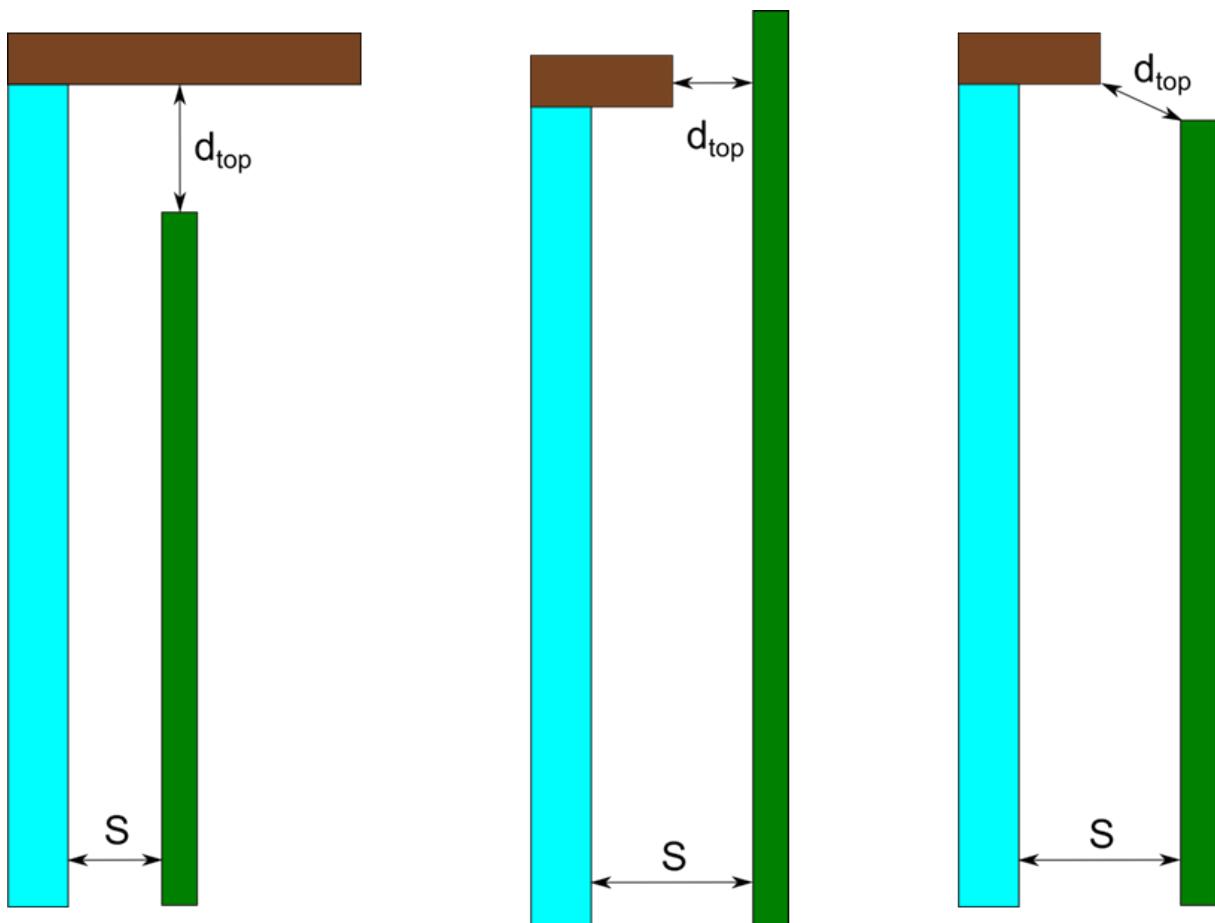

Figure 1.17: Three cases for the  $D_{top}$  calculation for an indoor/outdoor shade: Case a) A shading device between the frame; Case b) A shading device outside the frame, covering the frame; Case c) a shading device outside the frame, not covering the frame.

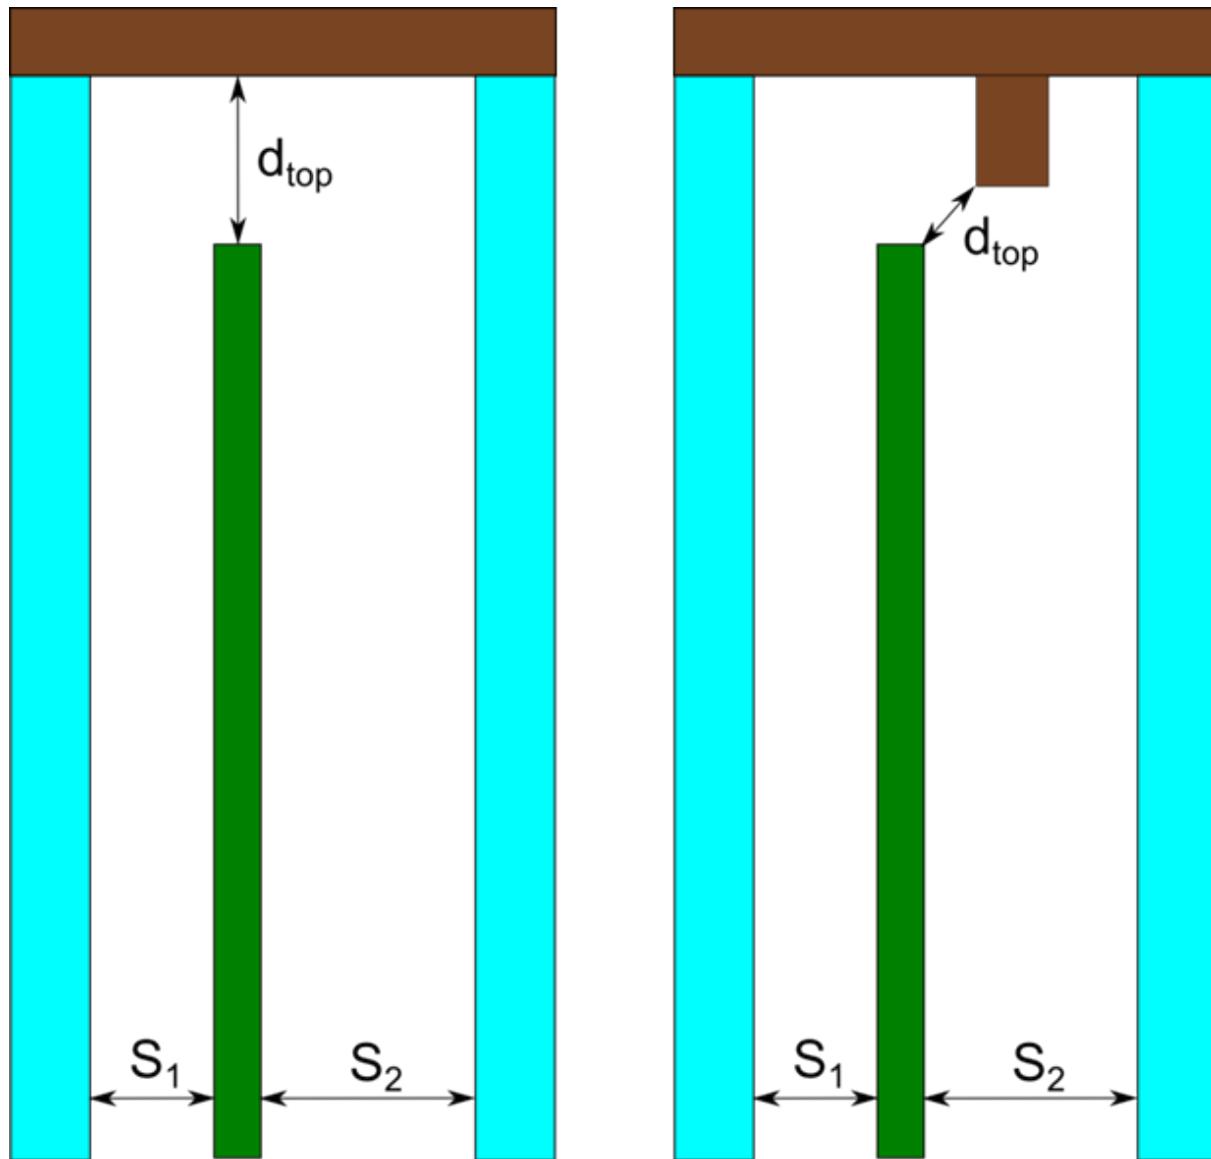

Figure 1.18: Calculation of  $d_{top}$  for a shading device between glass layers

### 1.9.30.1.10 Field: Left Side Opening Multiplier

The left side opening multiplier ( $d_{left}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the left side of the shading device.

### 1.9.30.1.11 Field: Right Side Opening Multiplier

The right side opening multiplier ( $d_{right}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the right side of the shading device.

### 1.9.30.1.12 Field: Front Opening Multiplier

The fraction of glazing system area that is open on the front of the shading layer (see Figure 1.19). This fraction is calculated as follows:  $A_{front} / (W * H)$ , where  $A_{front}$  = Area of the front of the glazing system that is not covered by the shading system,  $W$  = the width of the glazing system (IGU) and  $H$  is height of the glazing system (IGU).

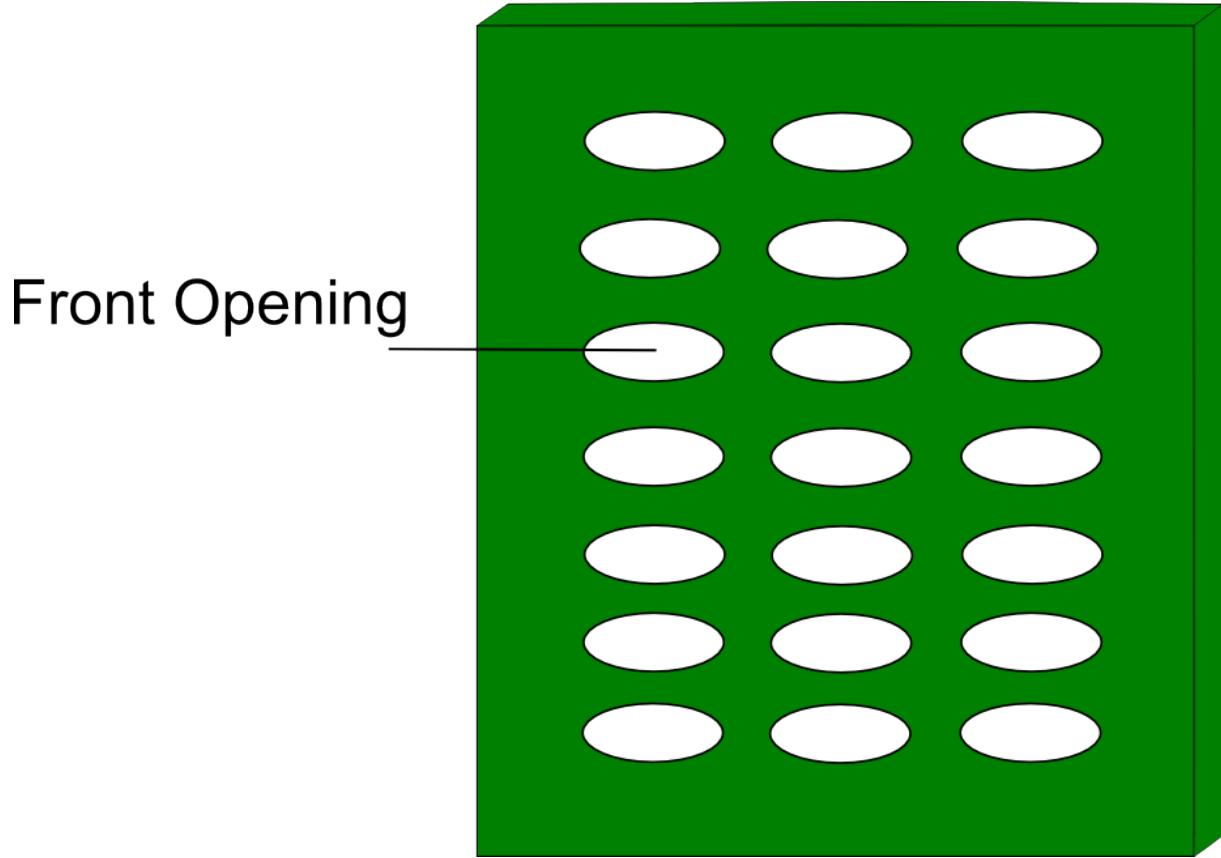

Figure 1.19: Front view of shading layer openings.

### 1.9.30.1.13 Field: Slat Width

The width (m) of the venetian slats. Used only for ShadingLayerType = Venetian.

### 1.9.30.1.14 Field: Slat Spacing

The distance (m) between front sides of the venetian slats. Used only for ShadingLayerType = Venetian.

#### 1.9.30.1.15 Field: Slat Thickness

The thickness (m) of the venetian slats. Used only for ShadingLayerType = Venetian.

#### 1.9.30.1.16 Field: Slat Angle

The slat tilt angle (degrees) of the venetian slats. Used only for ShadingLayerType = Venetian. Range of slat angle is from -90 to 90 degrees.

#### 1.9.30.1.17 Field: Slat Conductivity

The conductivity (W/mK) of the venetian slats. Used only for ShadingLayerType = Venetian.

#### 1.9.30.1.18 Field: Slat Curve

The curvature radius (m) of the venetian slats. Setting this value to zero means there is no curvature in the slat (it is flat), while a non-zero value is the radius of the slat curve. This value cannot be smaller than Slat Width / 2. Used only for ShadingLayerType = Venetian.

An IDF example for ShadingLayerType = Venetian

```
WindowMaterial:ComplexShade,      !- venetian blind layer
  Shade_30001_Layer,            !- name

### 1.9.31 WindowMaterial:Screen

This object specifies the properties of exterior window screen materials. The window screen model assumes the screen is made up of intersecting orthogonally-crossed cylinders. The surface of the cylinders is assumed

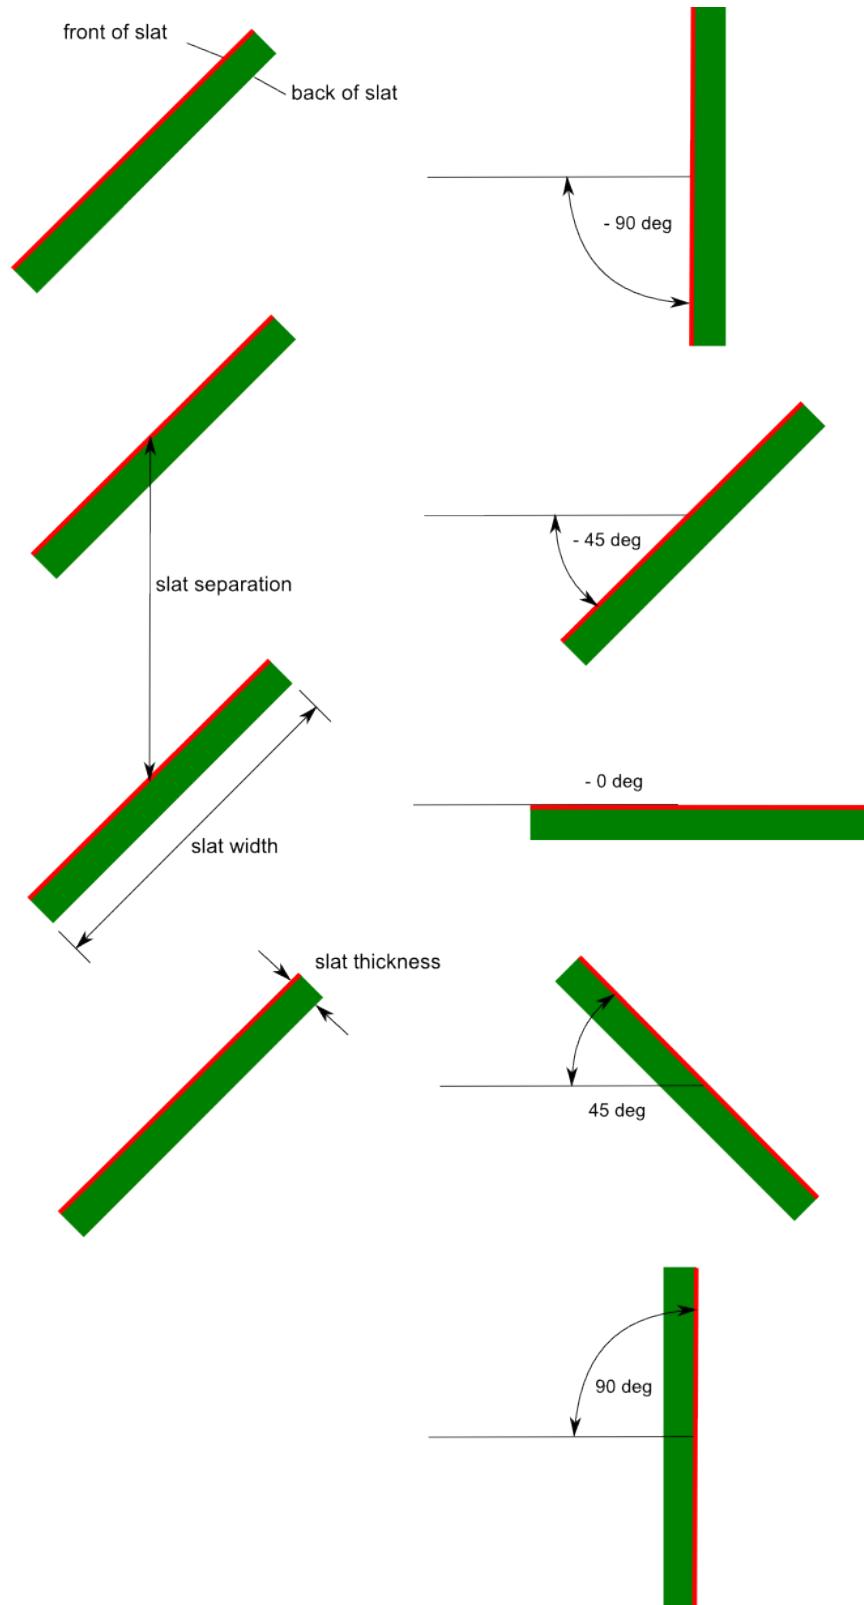

Figure 1.20: Side view of horizontal venetian blind slats or top view of blinds with vertical slats. Front face of slats is marked with red line.

to be diffusely reflecting, having the optical properties of a Lambertian surface.

The beam solar radiation transmitted through a window screen varies with sun angle and is made up of two distinct elements: a direct beam component and a reflected beam component. The direct beam transmittance component is modeled using the geometry of the screen material and the incident angle of the sun to account for shadowing of the window by the screen material. The reflected beam component is an empirical model that accounts for the inward reflection of solar beam off the screen material surface. This component is both highly directional and small in magnitude compared to the direct beam transmittance component (except at higher incident angles, for which case the magnitude of the direct beam component is small or zero and the reflected beam component, though small in absolute terms can be many times larger than the direct beam component). For this reason, the reflected beam transmittance component calculated by the model can be a. disregarded, b. treated as an additive component to direct beam transmittance (and in the same direction), or c. treated as hemispherically-diffuse transmittance based on a user input to the model.

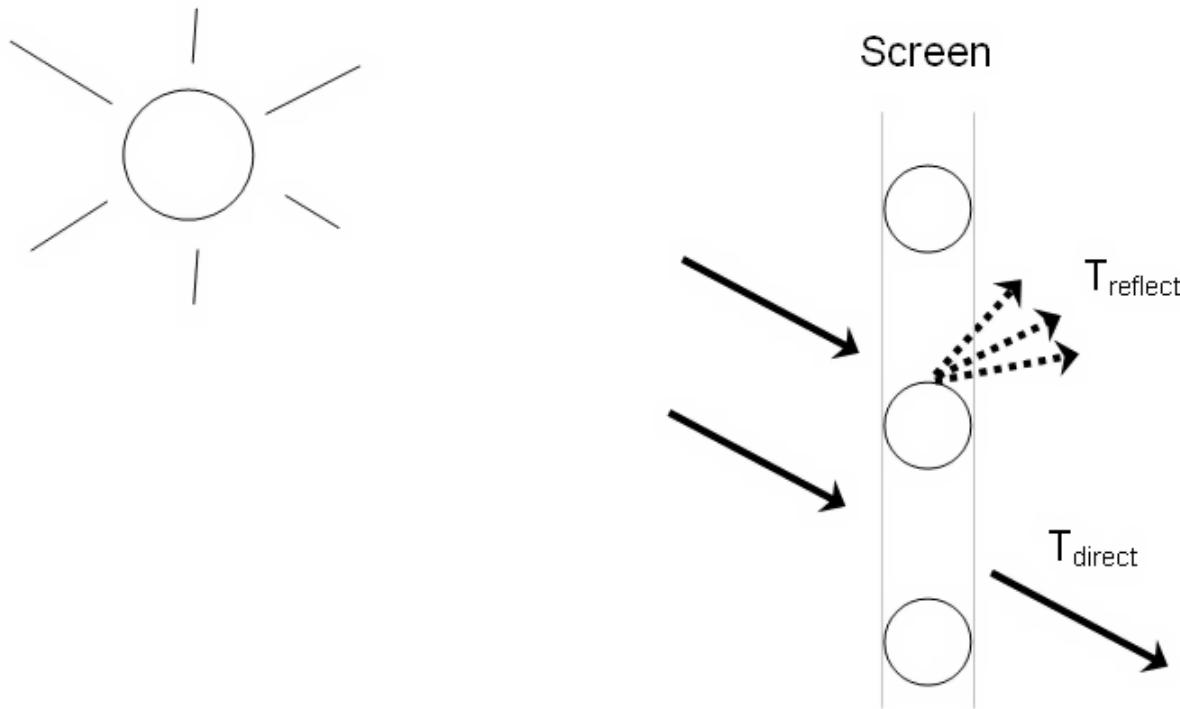

Figure 1.21: Direct beam and reflected beam transmittance components

The window screen “assembly” properties of overall beam solar reflectance and absorptance (including the screen material ‘cylinders’ and open area) also change with sun angle and are calculated based on the values of the beam solar transmittance components (direct and reflected components described above) and the physical properties of the screen material (i.e., screen material diameter, spacing, and reflectance).

Transmittance, reflectance, and absorptance of diffuse solar radiation are considered constant values and apply to both the front and back surfaces of the screen. These properties are calculated by the model as an average value by integrating the screen’s beam solar properties over a quarter hemisphere of incident radiation. Long-wave emissivity is also assumed to be the same for both sides of the screen.

There is an EnergyPlus Reference Data Set for WindowMaterial:Screen that contains properties for generic window screens. Window screens of this type can only be used on the outside surface of the window (“exterior screens”). When in place, the screen is assumed to cover all of the glazed part of the window,

including dividers; it does not cover any of the window frame, if present. The plane of the screen is assumed to be parallel to the glazing.

`WindowMaterial:Screen` can be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation. For diffusing materials such as drapery and translucent roller shades it is better to use the `WindowMaterial:Shade` object. For slat-type shading devices like Venetian blinds, which have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation, it is better to use `WindowMaterial:Blind`.

There are two methods of assigning a screen to a window:

### 1.9.31.1 Inputs

#### 1.9.31.1.1 Method 1:

- 1) Define the construction of the window without the screen, the so-called “bare” construction.
- 2) Reference the bare construction in the `FenestrationSurface:Detailed` for the window.
- 3) Define the `WindowMaterial:Screen` object.
- 4) Define a `WindowShadingControl` for the window in which you (a) specify that this `Material:WindowScreen` is the window’s shading device, and (b) specify how the screen is controlled.

#### 1.9.31.1.2 Method 2:

- 1) Define the Construction of the window without the screen, the so-called “bare” construction.
- 2) Reference the bare construction in the `FenestrationSurface:Detailed` for the window.
- 3) Define the `WindowMaterial:Screen` object.
- 4) Define another Construction, called the “shaded construction,” that includes the `WindowMaterial:Screen`.
- 5) Define a `WindowShadingControl` for the window in which you (a) reference the shaded construction, and (b) specify how the screen is controlled.

Note that `WindowShadingControl` has to be used with either method, even if the screen is in place at all times. You will get an error message if you try to reference a shaded construction directly from a `FenestrationSurface:Detailed` object.

#### 1.9.31.1.3 Field: Name

Enter a unique name for the screen. This name is referenced as an outside layer in a window construction.

#### 1.9.31.1.4 Field: Reflected Beam Transmittance Accounting Method

This input specifies the method used to account for screen-reflected beam solar radiation that is transmitted through the window screen (as opposed to being reflected back outside the building). Since this inward reflecting beam solar is highly directional and is not modeled in the direction of the actual reflection, the user is given the option of how to account for the directionality of this component of beam solar transmittance. Valid choices are `DoNotModel`, `ModelAsDirectBeam` (i.e., model as an additive component to direct solar beam and in the same direction), or `ModelAsDiffuse` (i.e., model as hemispherically-diffuse radiation). The default value is `ModelAsDiffuse`.

#### 1.9.31.1.5 Field: Diffuse Solar Reflectance

This input specifies the solar reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The outgoing diffuse radiation is assumed to be Lambertian (distributed angularly according to Lambert’s cosine law). The solar reflectance is assumed to be the same for both sides of the screen. This value must be from 0

to less than 1.0. In the absence of better information, the input value for diffuse solar reflectance should match the input value for diffuse visible reflectance.

#### 1.9.31.1.6 Field: Diffuse Visible Reflectance

This input specifies the visible reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material) averaged over the solar spectrum and weighted by the response of the human eye. The outgoing diffuse radiation is assumed to be Lambertian (distributed angularly according to Lambert’s cosine law). The visible reflectance is assumed to be the same for both sides of the screen. This value must be from 0 to less than 1.0.

If diffuse visible reflectance for the screen material is not available, then the following guidelines can be used to estimate this value:

- Dark-colored screen (e.g., charcoal):                    0.08 – 0.10
- Medium-colored screen (e.g., gray):                    0.20 – 0.25
- Light-colored screen (e.g., bright aluminum):        0.60 – 0.65

Commercially-available gray scale or grayscale reflecting chart references can be purchased for improved accuracy in estimating visible reflectance (by visual comparison of screen reflected brightness with that of various known-reflectance portions of the grayscale).

#### 1.9.31.1.7 Field: Thermal Hemispherical Emissivity

Long-wave emissivity  $\varepsilon$  of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The emissivity is assumed to be the same for both sides of the screen.

For most non-metallic materials,  $\varepsilon$  is about 0.9. For metallic materials,  $\varepsilon$  is dependent on material, its surface condition, and temperature. Typical values for metallic materials range from 0.05 – 0.1 with lower values representing a more finished surface (e.g. low oxidation, polished surface). Material emissivities may be found in Table 1.11 from the 2005 ASHRAE Handbook of Fundamentals, page 3.9. The value for this input field must be between 0 and 1, with a default value of 0.9 if this field is left blank.

#### 1.9.31.1.8 Field: Conductivity

Screen material conductivity (W/m-K). This input value must be greater than 0. The default value is 221 W/m-K (aluminum).

#### 1.9.31.1.9 Field: Screen Material Spacing

The spacing, S, of the screen material (m) is the distance from the center of one strand of screen to the center of the adjacent one. The spacing of the screen material is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than the non-zero screen material diameter. If the spacing is different in the two directions, use the average of the two values.

#### 1.9.31.1.10 Field: Screen Material Diameter

The diameter, D, of individual strands or wires of the screen material (m). The screen material diameter is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than 0 and less than the screen material spacing. If the diameter is different in the two directions, use the average of the two values.

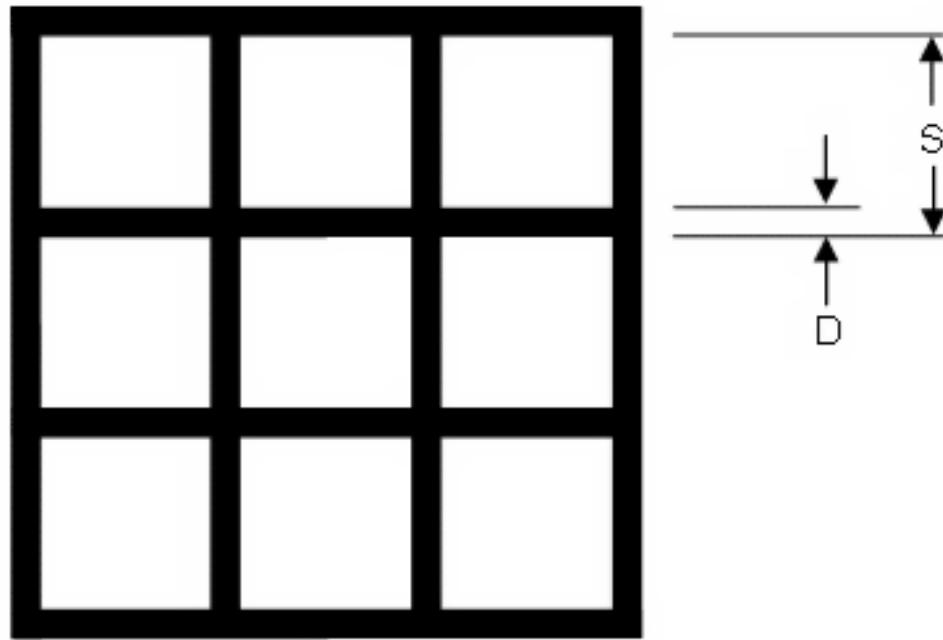

Figure 1.22: Screen Material Spacing and Diameter

#### 1.9.31.1.11 Field: Screen to Glass Distance

Distance from the window screen to the adjacent glass surface (m). If the screen is not flat, the average screen to glass distance should be used. The screen-to-glass distance is used in calculating the natural convective air flow between the glass and the screen produced by buoyancy effects. This input value must be from 0.001 m to 1 m, with a default value of 0.025 m if this field is left blank.

#### 1.9.31.1.12 Field: Top Opening Multiplier

Effective area for air flow at the top of the screen divided by the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.9.31.1.13 Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the screen divided the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.9.31.1.14 Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

### 1.9.31.1.15 Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

### 1.9.31.1.16 Field: Angle of Resolution for Screen Transmittance Output Map

Angle of resolution, in degrees, for the overall screen beam transmittance (direct and reflected) output map. The comma-separated variable file eplusscreen.csv (Ref. OutputDetailsandExamples.pdf) will contain the direct beam and reflected beam solar radiation that is transmitted through the window screen as a function of incident sun angle (0 to 90 degrees relative solar azimuth and 0 to 90 degrees relative solar altitude) in sun angle increments specified by this input field. The default value is 0, which means no transmittance map is generated. Other valid choice inputs are 1, 2, 3 and 5 degrees.

An IDF example for this object, along with Construction and **WindowShadingControl** objects, is shown below:

## 1.9.32 WindowMaterial:Shade:EquivalentLayer

This object specifies the properties of Equivalent Layer window shade (roller blind) materials. Shades are considered to be thin, flat and perfect diffusers (all transmitted and reflected radiation is hemispherically-diffuse). However, shades can have beam-beam transmittance by virtue of their material openness. The beam-beam transmittance is assumed to be the same for both sides of the shade and is the same as the openness area fraction. Beam-diffuse transmittance and reflectance, and emissivity properties can be different for front and back side of the shade. Window shades can be placed on the inside of the window, on the outside of the window, or between glass layers. WindowMaterial:Shade:EquivalentLayer is used for roller blinds. The off-normal solar property calculation of shades (roller blind) is based on a set of correlations developed from measurement of samples of commercially produced roller blind material with openness fraction less than 0.14. The model is not intended for materials with unusually high values of openness and should be limited to a maximum openness fraction of 0.20. The visible spectrum solar properties input fields are not used currently hence can be left blank. The equivalent layer window shade model does not support [WindowShadingControl](#).

### 1.9.32.1 Inputs

#### 1.9.32.1.1 Field: Name

Name of the shade. It is referenced as an inside, inbetween or outside layer in an equivalent layer window construction.

#### 1.9.32.1.2 Field: Shade Beam-Beam Solar Transmittance

This value is the beam-beam transmittance of the shade at normal incidence and it is the same as the openness area fraction of the shade material. Assumed to be the same for front and back sides of the roller blinds. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. For most common shade materials (e.g. Roller Blinds) the material openness fraction doesn't exceed 0.20.

#### 1.9.32.1.3 Field: Front Side Shade Beam-Diffuse Solar Transmittance

This value is the front side beam-diffuse transmittance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0.

#### 1.9.32.1.4 Field: Back Side Shade Beam-Diffuse Solar Transmittance

This value is the back side beam-diffuse transmittance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0.

#### 1.9.32.1.5 Field: Front Side Shade Beam-Diffuse Solar Reflectance

This value is the front side beam-diffuse reflectance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.32.1.6 Field: Back Side Shade Beam-Diffuse Solar Reflectance

This value is the back side beam-diffuse reflectance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.32.1.7 Field: Shade Beam-Beam Visible Transmittance

This value is the beam-beam transmittance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.9.32.1.8 Field: Shade Beam-Diffuse Visible Transmittance

This value is the beam-diffuse transmittance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.9.32.1.9 Field: Shade Beam-Diffuse Visible Reflectance

This value is the beam-diffuse reflectance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.9.32.1.10 Field: Shade Material Infrared Transmittance

This value is the long-wave transmittance of the shade material and assumed to be the same for front and back sides of the shade. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.05.

#### 1.9.32.1.11 Field: Front Side Shade Material Infrared Emissivity

This value is the front side long-wave hemispherical emissivity of shade material. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.91. The front side effective emissivity of the shade layer is calculated using this value and the material openness specified above.

#### 1.9.32.1.12 Field: Back Side Shade Material Infrared Emissivity

This value is the back side long-wave hemispherical emissivity of shade material. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.91. The back side effective emissivity of the shade is calculated using this value and the material openness specified above.

An IDF example for this object is shown below:

```
WindowMaterial:Shade:EquivalentLayer,
  Shade1,           !- Name
  0.190,            !- Shade Beam-Beam Solar Transmittance

```

### 1.9.33 WindowMaterial:Drape:EquivalentLayer

Specifies the optical and thermal properties of equivalent layer window drape fabric materials.

Drapery fabric shades are commonly placed on the the inside of the window. The long-wave (Thermal) properties for commonly used drapery fabrics are assumed to be the same on both sides but different values can be specified when required. Drape fabric shade layers are considered to be perfect diffusers (reflected

radiation is hemispherically-diffuse independent of angle of incidence). Unpleated drape fabric is treated as thin and flat layer. The off-normal optical properties of drapery fabric is determined from user specified optical properties at normal incidence using empirical correlations. Pleated drape fabric requires entering the pleated section average width and length as shown in Figure 1.23. For pleated drapes the effective beam-beam and beam-diffuse solar properties are determined by tracking both radiation components, for a given incident angle solar radiation, through various interactions with a fabric pleated in a rectangular geometry shown in Figure 1.23. The solar properties of the two different pleat facets are evaluated on the basis of the local solar incidence angle. Therefore, the effective layer properties are influenced not just by horizontal solar profile angle, but also by incidence angle. The correlations used for drape fabrics optical property calculations require that the solar absorptance of the fabric, at normal incidence, is not less than 1%. The equivalent layer window drapery fabric shade model does not support [WindowShadingControl](#).

### 1.9.33.1 Inputs

#### 1.9.33.1.1 Field: Name

Name of the drape fabric shade layer. It is referenced as an inside, in between or outside layer in an equivalent layer window construction.

#### 1.9.33.1.2 Field: Drape Beam-Beam Solar Transmittance

This value is the drape fabric beam-beam transmittance at normal incidence, and it is the same as the drape fabric openness area fraction. Assumed to be the same for front and back sides of the drape fabric layer. The minimum value is 0.0 and maximum value is less than 1.0. For most drape fabric materials the maximum fabric openness fraction do not exceed 0.2. The default value is 0.0.

#### 1.9.33.1.3 Field: Front Side Drape Beam-Diffuse Solar Transmittance

This value is the front side beam-diffuse solar transmittance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.33.1.4 Field: Back Side Drape Beam-Diffuse Solar Transmittance

This value is the back side beam-diffuse solar transmittance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.33.1.5 Field: Front Side Drape Beam-Diffuse Solar Reflectance

This value is the front side beam-diffuse solar reflectance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.33.1.6 Field: Back Side Drape Beam-Diffuse Solar Reflectance

This value is the back side beam-diffuse solar reflectance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.9.33.1.7 Field: Drape Beam-Beam Visible Transmittance

This value is the drape fabric beam-beam visible transmittance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape fabric layer. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

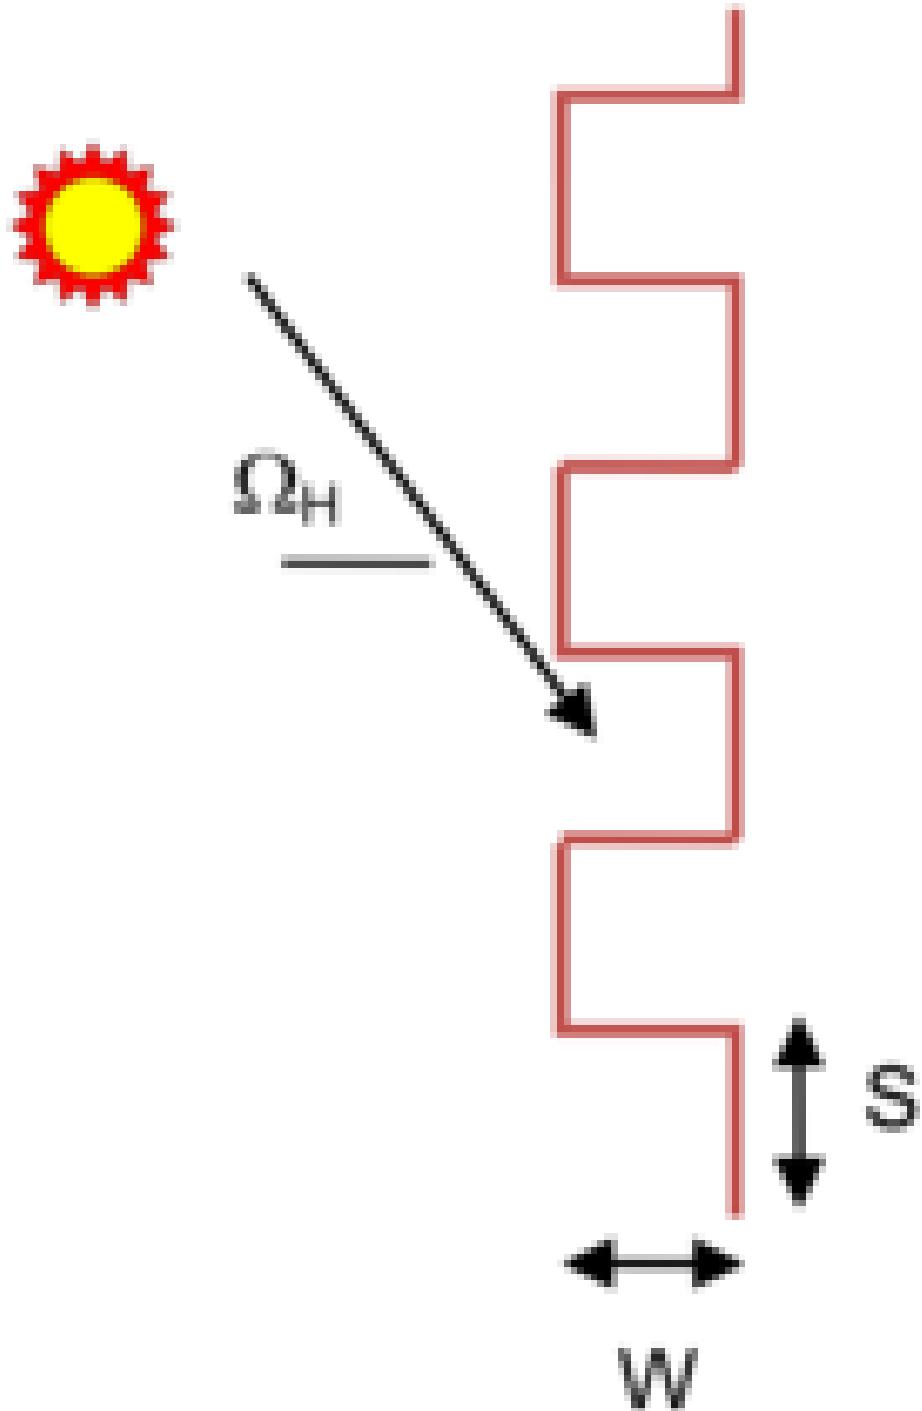

Figure 1.23: Geometry used for Pleated Drape Analysis

#### 1.9.33.1.8 Field: Front Side Drape Beam-Diffuse Visible Reflectance

This value is the front side drape fabric beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

#### 1.9.33.1.9 Field: Back Side Drape Diffuse-Diffuse Visible Reflectance

This value is the back side drape fabric diffuse-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

#### 1.9.33.1.10 Field: Drape Material Infrared Transmittance

This value is the long-wave hemispherical transmittance of the fabric material at zero fabric openness fraction. Assumed to be the same for front and back sides of the drape fabric material layer. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.05.

#### 1.9.33.1.11 Field: Front Side Drape Material Infrared Emissivity

This value is the front side long-wave hemispherical emissivity of fabric material at zero shade openness. The minimum value is 0.0 and maximum value is less than 1.0. the default value is 0.87. The front side effective emissivity of the drape fabric layer is calculated using this value and the fabric openness area fraction specified above.

#### 1.9.33.1.12 Field: Back Side Drape Material Infrared Emissivity

This value is the back side long-wave hemispherical emissivity of fabric material at zero fabric openness fraction. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.87. The back side effective emissivity of the drape fabric layer is calculated using this value and the fabric openness area fraction specified above.

#### 1.9.33.1.13 Field: Width of Pleated Fabric

This value is the width of the pleated section of the draped fabric, w(m). If the drape fabric is flat (unpleated), then the pleated section width is set to zero. The default value is 0.0, i.e., assumes flat drape fabric.

#### 1.9.33.1.14 Field: Length of Pleated Fabric

This value is the length of the pleated section of the draped fabric, s(m). If the drape fabric is flat (unpleated), then the pleated section length is set to zero. The default value is 0.0, i.e., assumes flat drape fabric.

An IDF example for this object is shown below:

## 1.9.34 WindowMaterial:Blind:EquivalentLayer

This object specifies the properties of an Equivalent Layer window blind consisting of thin and equally-spaced slats. The model assumes that slats are flat and thin, and applies correction for the slat curvature effect based on the user specified slat crown. Slats are assumed to transmit and reflect diffusely. The effective shortwave optical and longwave optical properties of venetian blind layer is estimated analytically. The Equivalent Layer blind model requires optical properties and geometry of the slats shown in Figure 1.24. Likewise, effective longwave properties are obtained for the layer knowing longwave properties of the slats.

The input data required to characterize a venetian blind are: front and back side reflectance and transmittance of the slat, geometry (Slat width, w, slat spacing, s, slat crown, c, and slat angle,  $\phi$ , and long wave emittance and transmittance of the slat. Blinds can be located on the inside of the window, on the outside of the window, or between two layers of glass. The blind is assumed to cover all of the glazed part of the window. The equivalent layer window blind model allows three slat angle control types (see *Slat Angle Control* input field) but does not support *WindowShadingControl*.

### 1.9.34.1 Inputs

#### 1.9.34.1.1 Field: Name

Name of the venetian blind. It is referenced as an inside, outside or in between layers in an equivalent layer window construction.

#### 1.9.34.1.2 Field: Slat Orientation

The choices are Horizontal and Vertical. “Horizontal” means the slats are parallel to the bottom of the window; this is the same as saying that the slats are parallel to the X-axis of the window. “Vertical” means the slats are parallel to Y-axis of the window. The default is “Horizontal”.

#### 1.9.34.1.3 Field: Slat Width

This value is the width of the slat measured from edge to edge (m). The default value is 0.0254.

#### 1.9.34.1.4 Field: Slat Separation

The distance between the front of a slat and the back of the adjacent slat (m). The default value is 0.025. The slat separation should not be greater than the slat width.

#### 1.9.34.1.5 Field: Slat Crown

The perpendicular length between the slat cord and the curve (m). Crown = 0.0625x“Slat width”. Slat is assumed to be rectangular in cross section and flat. The crown accounts for curvature of the slat. The minimum value is 0.0, and the default value is 0.0015m.

#### 1.9.34.1.6 Field: Slat Angle

The angle (degrees) between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat (degrees). The slat angle is +ve if the tip of the slat front face is tilted upward, or else the slat angle is -ve if the tip of the slat front face is tilted downward. The slat angle varies between -90 to +90. If the ‘*Slat Angle Control*’ input field below specified is “FixedSlatAngle”, then the slat angle is fixed at “Slat Angle” value entered. Minimum value allowed is -90.0, and the maximum value allowed is 90.0 degrees. The default value is 45 degrees.

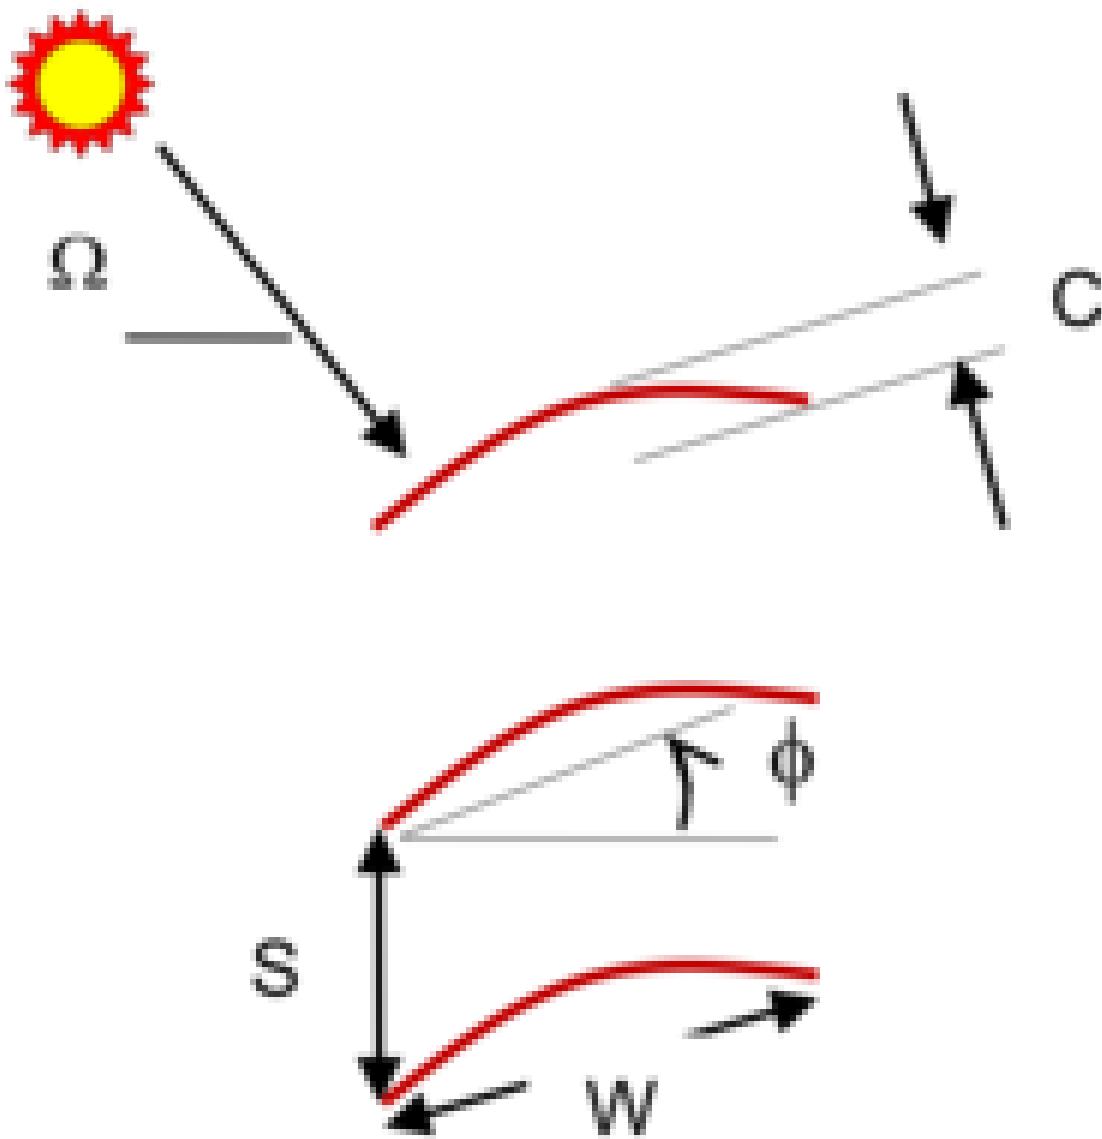

Figure 1.24: Geometry and Properties used for venetian blind analysis

**1.9.34.1.7 Field: Front Side Slat Beam-Diffuse Solar Transmittance**

This value is the slat front side beam-diffuse solar transmittance at normal incidence averaged over the entire spectrum of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

**1.9.34.1.8 Field: Back Side Slat Beam-Diffuse Solar Transmittance**

This value is the slat back side beam-diffuse solar transmittance at normal incidence averaged over the entire spectrum of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

**1.9.34.1.9 Field: Front Side Slat Beam-Diffuse Solar Reflectance**

This value is slat front side beam-diffuse solar reflectance at normal incidence averaged over the entire spectrum of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.34.1.10 Field: Back Side Slat Beam-Diffuse Solar Reflectance**

This value is the slat back side beam-diffuse solar reflectance at normal incidence averaged over the entire spectrum of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.34.1.11 Field: Front Side Slat Beam-Diffuse Visible Solar Transmittance**

This value is the slat front side beam-diffuse visible transmittance at normal incidence averaged over the visible spectrum range of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

**1.9.34.1.12 Field: Back Side Slat Beam-Diffuse Visible Solar Transmittance**

This value is the slat back side beam-diffuse visible transmittance at normal incidence averaged the visible spectrum range of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

**1.9.34.1.13 Field: Front Side Slat Beam-Diffuse Visible Solar Reflectance**

This value is the slat front side beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0

**1.9.34.1.14 Field: Back Side Slat Beam-Diffuse Visible Solar Reflectance**

This value is the slat back side beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0

**1.9.34.1.15 Field: Slat Diffuse-Diffuse Solar Transmittance**

This value is the slat diffuse-diffuse solar transmittance for hemispherically diffuse solar radiation. This value is the same for front and back side of the slat. Minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.34.1.16 Field: Front Side Slat Diffuse-Diffuse Solar Reflectance

This value is the slat front side diffuse-diffuse solar reflectance for hemispherically diffuse solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.34.1.17 Field: Back Side Slat Diffuse-Diffuse Solar Reflectance

This value is the slat back side diffuse-diffuse solar reflectance for hemispherically diffuse solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.34.1.18 Field: Slat Diffuse-Diffuse Visible Transmittance

This value is the slat diffuse-diffuse visible transmittance for hemispherically diffuse visible spectrum range of solar radiation. This value is the same for front and back side of the slat. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### 1.9.34.1.19 Field: Front Side Slat Diffuse-Diffuse Visible Reflectance

This value is the slat front side diffuse-diffuse visible reflectance for hemispherically diffuse visible spectrum range of solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### 1.9.34.1.20 Field: Back Side Slat Diffuse-Diffuse Visible Reflectance

This value is the slat back side diffuse-diffuse visible reflectance for hemispherically diffuse visible spectrum range of solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### 1.9.34.1.21 Field: Slat Infrared Transmittance

This value is the long-wave hemispherical transmittance of the slat material. Assumed to be the same for both sides of the slat. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.0.

#### 1.9.34.1.22 Field: Front Side Slat Infrared Emissivity

This value is the front side long-wave hemispherical emissivity of the slat material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.9.

#### 1.9.34.1.23 Field: Back Side Slat Infrared Emissivity

This value is the back side long-wave hemispherical emissivity of the slat material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.9.

#### 1.9.34.1.24 Field: Slat Angle Control

This input field is used only if slat angle control is desired. The three key choice inputs allowed are “FixedSlatAngle”, “MaximizeSolar”, and “BlockBeamSolar”. The default value is “FixedSlatAngle”. If Type of Slat Angle Control for Blinds = MaximizeSolar the slat angle is adjusted to maximize solar gain. If Type of Slat Angle Control for Blinds = BlockBeamSolar, the slat angle is adjusted to maximize visibility while eliminating beam solar radiation. If Type of Slat Angle Control for Blinds = FixedSlatAngle, then the model uses a fixed slat angle specified above.

An IDF example for this object, is shown below:

### 1.9.35 WindowMaterial:Screen:EquivalentLayer

This object specifies the optical and thermal properties of exterior screen materials for Equivalent Layer Window. Can only be placed on the exterior side of window construction. The window screen model assumes the screen is made up of intersecting orthogonally-crossed cylinders. The surface of the cylinders is assumed to be diffusely reflecting. The beam solar radiation transmitted through an equivalent Layer window screen varies with sun angle and is made up of two distinct elements: a beam-beam component and a beam-diffuse component. The beam-beam transmittance component is calculated using screen openness area fraction determined from the geometry of the screen and the incident angle of the sun. Empirical correlations are used to obtain the effective off-normal solar and longwave properties of insect screens. Insect screen geometry is shown in Figure 1.25. The calculation of effective solar properties requires a set of properties measured at normal incidence. The equivalent layer window screen shade model does not support **WindowShadingControl**.

The formulation of the model, assumption and correlations used to calculate effective solar and longwave properties of insect screens are described in the Engineering Reference.

#### 1.9.35.1 Inputs

##### 1.9.35.1.1 Field: Name

Name of the insect screen. It is referenced as an outside layer in an equivalent layer window construction.

##### 1.9.35.1.2 Field: Screen Beam-Beam Solar Transmittance

This value is the beam-beam transmittance of the screen material at normal incidence. This value is the same as the screen openness area fraction. This value can be autocalculated from the wire spacing and wire diameter. It is the same for both sides of the screen. The minimum value is 0.0, and maximum value is less than 1.0.

##### 1.9.35.1.3 Field: Screen Beam-Diffuse Solar Transmittance

This value is the beam-diffuse solar transmittance of the screen material at normal incidence averaged over the entire spectrum of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0.

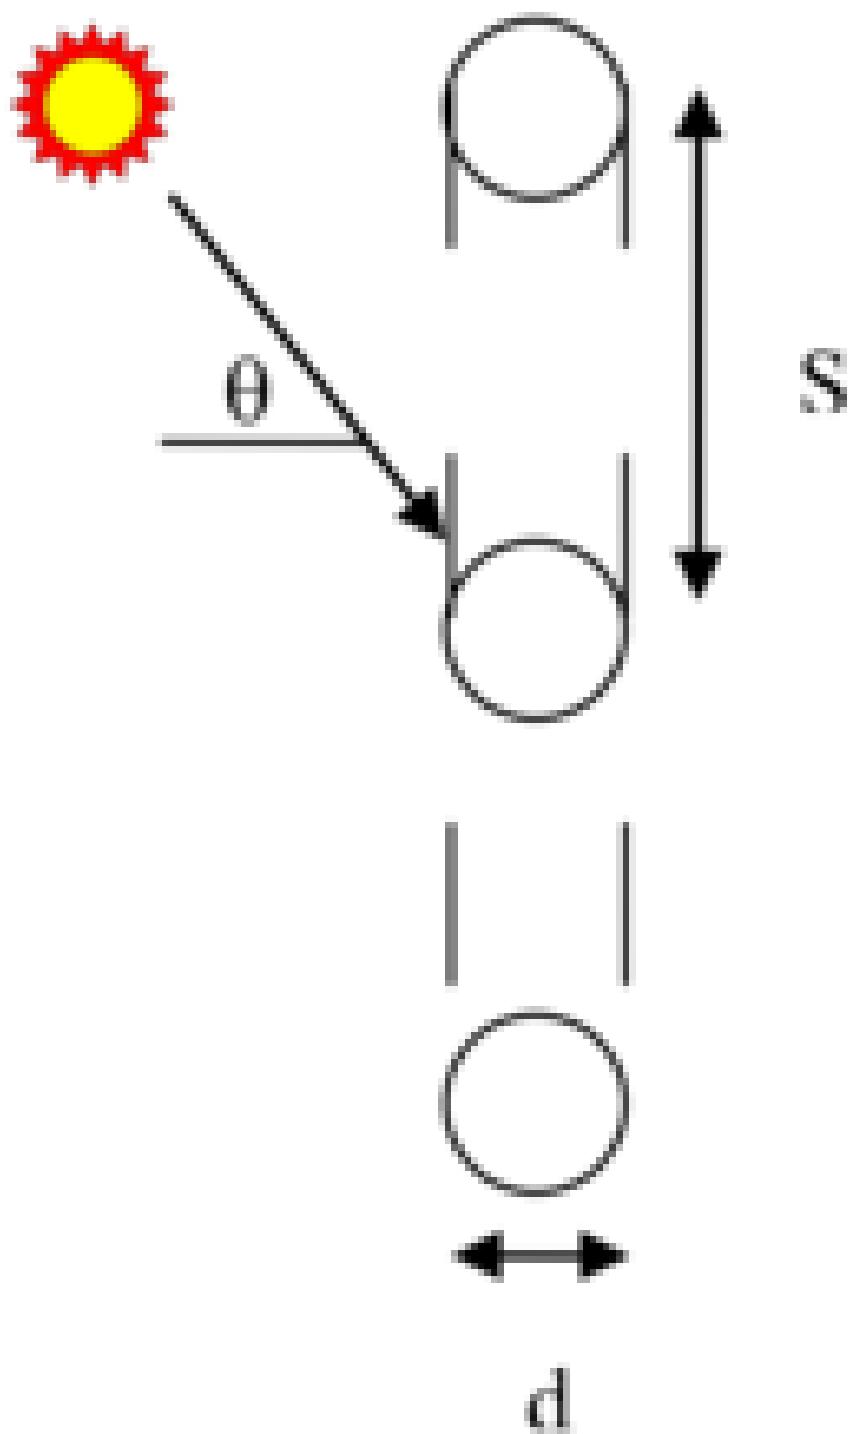

Figure 1.25: Geometry used for insect screen analysis

#### **1.9.35.1.4 Field: Screen Beam-Diffuse Solar Reflectance**

This value is the beam-diffuse solar reflectance of the screen material at normal incidence averaged over the entire spectrum of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.9.35.1.5 Field: Screen Beam-Beam Visible Transmittance**

This value is the beam-beam visible transmittance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and maximum value is less than 1.0. This input field is not used currently.

#### **1.9.35.1.6 Field: Screen Beam-Diffuse Visible Transmittance**

This value is the beam-diffuse visible reflectance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.9.35.1.7 Field: Screen Beam-Diffuse Visible Reflectance**

This value is the beam-diffuse visible reflectance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.9.35.1.8 Field: Screen Infrared Transmittance**

This value is the long-wave hemispherical transmittance of the screen material. Assumed to be the same for both sides of the screen material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.02

#### **1.9.35.1.9 Field: Screen Infrared Emissivity**

This value is the long-wave hemispherical emissivity of the screen material. Assumed to be the same for both sides of the screen material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.93.

#### **1.9.35.1.10 Field: Screen Wire Spacing**

The spacing, S (m), of the screen material is the distance from the center of one strand of screen to the center of the adjacent one. The spacing of the screen material is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than the non-zero screen material diameter. If the spacing is different in the two directions, use the average of the two values. Default value is 0.0025m.

#### **1.9.35.1.11 Field: Screen Wire Diameter**

The diameter, D (m), of individual strands or wires of the screen material. The screen material diameter is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than 0 and less than the screen wire spacing. If the diameter is different in the two directions, use the average of the two values. Default value is 0.005m.

## 1.9.36 WindowMaterial:Glazing:EquivalentLayer

Glass material properties for equivalent layer window model. Uses transmittance/reflectance input method. For exterior windows, “front side” is the side of the glass closest to the outside air and “back side” is the side closest to the zone the window is defined in. For interzone windows, “front side” is the side closest to the zone adjacent to the zone the window is defined in and “back side” is the side closest to the zone the window is defined in. The equivalent layer window glazing model does not support [WindowShadingControl](#).

### 1.9.36.1 Inputs

#### 1.9.36.1.1 Field: Name

The name of the glass layer. It corresponds to a layer in an equivalent layer window construction.

#### 1.9.36.1.2 Field: Optical Data Type

Valid values for this field are SpectralAverage, or Spectral. If Optical Data Type = SpectralAverage, the values you enter for solar transmittance and reflectance are assumed to be averaged over the solar spectrum, and the values you enter for visible transmittance and reflectance are assumed to be averaged over the solar spectrum and weighted by the response of the human eye. SpectralAverage is the default. Spectral data input is not supported now.

#### 1.9.36.1.3 Field: Window Glass Spectral Data Set Name

This input field is not used currently.

#### 1.9.36.1.4 Field: Front Side Beam-Beam Solar Transmittance

This value is the front side beam-beam solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.36.1.5 Field: Back Side Beam-Beam Solar Transmittance

This value is the back side beam-beam solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.36.1.6 Field: Front Side Beam-Beam Solar Reflectance

This value is the front side beam-beam solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.7 Field: Back Side Beam-Beam Solar Reflectance**

This value is the back side beam-beam solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.8 Field: Front Side Beam-Beam Visible Transmittance**

This value is the front side beam-beam visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.9 Field: Back Side Beam-Beam Visible Transmittance**

This value is the back side beam-beam visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.10 Field: Front Side Beam-Beam Visible Reflectance**

This value is the front side beam-beam visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.11 Field: Back Side Beam-Beam Visible Reflectance**

This value is the back side beam-beam visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.9.36.1.12 Field: Front Side Beam-Diffuse Solar Transmittance**

This value is the front side beam-diffuse solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.9.36.1.13 Field: Back Side Beam-Diffuse Solar Transmittance**

This value is the back side beam-diffuse solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse solar transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.9.36.1.14 Field: Front Side Beam-Diffuse Solar Reflectance**

This value is the front side beam-diffuse solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.9.36.1.15 Field: Back Side Beam-Diffuse Solar Reflectance**

This value is the back side beam-diffuse solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

#### 1.9.36.1.16 Field: Front Side Beam-Diffuse Visible Transmittance

This value is the front side beam-diffuse visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse visible transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

#### 1.9.36.1.17 Field: Back Side Beam-Diffuse Visible Transmittance

This value is the back side beam-diffuse visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse visible transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

#### 1.9.36.1.18 Field: Front Side Beam-Diffuse Visible Reflectance

This value is the front side beam-diffuse visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

#### 1.9.36.1.19 Field: Back Side Beam-Diffuse Visible Reflectance

This value is the back side beam-diffuse visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

#### 1.9.36.1.20 Field: Diffuse-Diffuse Solar Transmittance

This value is the diffuse-diffuse solar transmittance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The diffuse-diffuse transmittance is assumed to be the same for both sides of the glazing. EnergyPlus automatically estimates the diffuse-diffuse solar transmittance from other inputs. If this input field is specified as “Autocalculate”, then the calculated transmittance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.36.1.21 Field: Front Side Diffuse-Diffuse Solar Reflectance

This value is the front side diffuse-diffuse solar reflectance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the diffuse-diffuse reflectance from other inputs. If this input field is specified as “Autocalculate”, then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.36.1.22 Field: Back Side Diffuse-Diffuse Solar Reflectance

This value is the back side diffuse-diffuse solar reflectance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the diffuse-diffuse reflectance from other inputs. If this input field is specified as “Autocalculate”, then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.9.36.1.23 Field: Diffuse-Diffuse Visible Solar Transmittance

This value is the diffuse-diffuse visible transmittance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The diffuse-diffuse

visible transmittance is assumed to be the same for both sides of the glazing. If this input field is specified as “Autocalculate”, then the calculated transmittance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.9.36.1.24 Field: Front Side Diffuse-Diffuse Visible Reflectance**

This value is the front side diffuse-diffuse visible reflectance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the front side diffuse-diffuse visible reflectance from front side beam-beam visible reflectance at normal incidence specified above. If this input field is specified as “Autocalculate”, then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.9.36.1.25 Field: Back Side Diffuse-Diffuse Visible Reflectance**

This value is the back side diffuse-diffuse visible reflectance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the back side diffuse-diffuse visible reflectance from back side beam-beam visible reflectance at normal incidence specified above. If this input field is specified as “Autocalculate”, then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.9.36.1.26 Field: Infrared Transmittance (applies to front and back)**

This value is the long-wave hemispherical transmittance of the glazing. Assumed to be the same for both sides of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.0.

#### **1.9.36.1.27 Field: Front Side Infrared Emissivity**

This value is the front side long-wave hemispherical emissivity of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.84.

#### **1.9.36.1.28 Field: Back Side Infrared Emissivity**

This value is the back side long-wave hemispherical emissivity of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.84.

#### **1.9.36.1.29 Field: Thermal Resistance**

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are ( $m^2\cdot K$ )/W. Thermal resistance must be greater than zero. The default value is 0.158 which is roughly equivalent to a single layer of 1/4" glass. This field is only used if this equivalent layer of glazing is being referenced for movable insulation.

An IDF example for this object, is shown below:

---

### 1.9.37 WindowMaterial:Gap:EquivalentLayer

This object is used in windows equivalent layer construction object and specifies the properties of the gap between the layers in multi-layer equivalent layer window object. There is an EnergyPlus Reference Data Set for Material:WindowGas that contains several types of gas. This object uses the gas types: Air, Argon, Xenon, Crypton, and Custom. For Custom gas type users are required to entering the thermophysical properties.

#### 1.9.37.1 Inputs

##### 1.9.37.1.1 Field: Name

The name of the gap. It refers to a layer in a window construction equivalent layer.

##### 1.9.37.1.2 Field: Gas Type

The type of gas. The choices allowed are AIR, ARGON, XENON, KRYPTON, or CUSTOM.

##### 1.9.37.1.3 Field: Thickness

The thickness (m) of the gap layer.

##### 1.9.37.1.4 Field: Gap Vent Type

This input field contains the valid key choice for gap vent type. The valid vent types are: Sealed, VentedIndoor, and VentedOutdoor. Sealed means the gap is enclosed and gas tight, i.e., no venting to indoor or outdoor environment. The gap types “VentedIndoor” and “VentedOutdoor” are used with gas type “Air” only. VentedIndoor means the air in the gap is naturally vented to indoor environment, and VentedOutdoor means the air in the gap is naturally vented to the outdoor environment.

##### 1.9.37.1.5 Properties for Custom Gas Types

The following entries are used only if Gas Type = Custom. The A, B and C coefficients are those in the following expression that gives a property value as a function of temperature in degrees K:

$$\text{Property} = \text{Coeff}_A + \text{Coeff}_B \times \text{Temperature}_K + \text{Coeff}_C \times \text{Temperature}_K^2 \quad (1.18)$$

##### 1.9.37.1.6 Field: Conductivity Coefficient A

The A coefficient for gas conductivity (W/m-K). Used only if Gas Type = Custom.

**1.9.37.1.7 Field: Conductivity Coefficient B**

The B coefficient for gas conductivity (W/m-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.37.1.8 Field: Conductivity Coefficient C**

The C coefficient for gas conductivity (W/m-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.9.37.1.9 Field: Viscosity Coefficient A**

The A coefficient for gas viscosity (kg/m-s). Used only if Gas Type = Custom.

**1.9.37.1.10 Field: Viscosity Coefficient B**

The B coefficient for gas viscosity (kg/m-s-K). Used only if Gas Type = Custom.

**1.9.37.1.11 Field: Viscosity Coefficient C**

The C coefficient for gas viscosity (kg/m-s-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.37.1.12 Field: Specific Heat Coefficient A**

The A coefficient for gas specific heat (J/kg-K). Used only if Gas Type = Custom.

**1.9.37.1.13 Field: Specific Heat Coefficient B**

The B coefficient for gas specific heat (J/kg-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.9.37.1.14 Field: Specific Heat Coefficient C**

The C coefficient for gas specific heat (J/kg-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.9.37.1.15 Field: Specific Heat Ratio**

The specific heat ratio for gas. Used only if Gas Type = Custom.

**1.9.37.1.16 Field: Molecular Weight**

The molecular weight for gas. The molecular weight is the mass of 1 mol of the substance. This has a numerical value which is the average molecular mass of the molecules in the substance multiplied by Avogadro's constant. (kg/kmol) (Shown in the IDD as g/mol for consistency)

**1.9.37.1.17 Field: Specific Heat Ratio**

The specific heat ratio for gas. The specific heat ratio of a gas is the ratio of the specific heat at constant pressure, to the specific heat at constant volume. Used only if Gas Type = Custom.

An IDF example for this object, is shown below:

```
WindowMaterial:Gap:EquivalentLayer,

```

## 1.9.38 Material:RoofVegetation

This definition must be used in order to simulate the green roof (ecoroof) model. The material becomes the outside layer in a green roof construction (see example below). In the initial release of the green roof model, only one material may be used as a green roof layer though, of course, several constructions using that material may be used. In addition, the model works only with the ConductionTransferFunction heat balance solution algorithm. This model was developed for low-sloped exterior surfaces (roofs). It is not recommended for high-sloped exterior surfaces (e.g., walls).

### 1.9.38.1 Inputs

#### 1.9.38.1.1 Field: Name

This field is a unique reference name that the user assigns to a particular ecoroof material. This name can then be referred to by other input data.

#### 1.9.38.1.2 Field: Height of Plants

This field defines the height of plants in units of meters. This field is limited to values in the range  $0.005 < \text{Height} < 1.00$  m. Default is .2 m.

#### 1.9.38.1.3 Field: Leaf Area Index

This is the projected leaf area per unit area of soil surface. This field is dimensionless and is limited to values in the range  $0.001 < \text{LAI} < 5.0$ . Default is 1.0. At the present time the fraction vegetation cover is calculated directly from LAI (Leaf Area Index) using an empirical relation. The user may find it necessary to increase the specified value of LAI in order to represent high fractional coverage of the surface by vegetation.

#### 1.9.38.1.4 Field: Leaf Reflectivity

This field represents the fraction of incident solar radiation that is reflected by the individual leaf surfaces (albedo). Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. Values for this field must be between 0.05 and 0.5. Default is .22. Typical values are .18 to .25.

#### 1.9.38.1.5 Field: Leaf Emissivity

This field is the ratio of thermal radiation emitted from leaf surfaces to that emitted by an ideal black body at the same temperature. This parameter is used when calculating the long wavelength radiant exchange at the leaf surfaces. Values for this field must be between 0.8 and 1.0 (with 1.0 representing “black body” conditions). Default is .95.

#### 1.9.38.1.6 Field: Minimum Stomatal Resistance

This field represents the resistance of the plants to moisture transport. It has units of s/m. Plants with low values of stomatal resistance will result in higher evapotranspiration rates than plants with high resistance. Values for this field must be in the range of 50.0 to 300.0. Default is 180.

#### 1.9.38.1.7 Field: Soil Layer Name

This field is a unique reference name that the user assigns to the soil layer for a particular ecoroof. This name can then be referred to by other input data. Default is **Green Roof Soil**.

#### 1.9.38.1.8 Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A keyword is expected in this field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options. Default is MediumRough.

#### 1.9.38.1.9 Field: Thickness

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive number. Depths of .10m (4 inches) and .15m (6 inches) are common. Default if this field is left blank is .1. Maximum is .7m. Must be greater than .05 m.

#### 1.9.38.1.10 Field: Conductivity of Dry Soil

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are W/(m-K). Thermal conductivity must be greater than zero. Typical soils have values from .3 to .5. The minimum is .2, the default is .35, and the maximum is 1.5.

#### 1.9.38.1.11 Field: Density of Dry Soil

This field is used to enter the density of the material layer in units of kg/m<sup>3</sup>. Density must be a positive quantity. Typical soils range from 400 to 1000 (dry to wet). Minimum is 300, maximum is 2000 and default if field is left blank is 1100.

#### 1.9.38.1.12 Field: Specific Heat of Dry Soil

This field represents the specific heat of the material layer in units of J/(kg-K). Note that these units are most likely different than those reported in textbooks and references which tend to use kJ/(kg-K) or J/(g-K). They were chosen for internal consistency within EnergyPlus. Only positive values of specific heat are allowed.

#### 1.9.38.1.13 Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength (>2.5 microns) radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions). Typical values are from .9 to .98. The default value for this field is 0.9.

#### 1.9.38.1.14 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation (0.3 to 2.537 microns) includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. Typical values are from .6 to .85. The default value for this field is 0.7.

### 1.9.38.1.15 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation ( 0.37 to 0.78 microns weighted by photopic response) is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.5 and 1.0. The default value for this field is 0.75.

### 1.9.38.1.16 Field: Saturation Volumetric Moisture Content of the Soil Layer

The field allows for user input of the saturation moisture content of the soil layer. Maximum moisture content is typically less than .5. Range is [.1,.5] with the default being .3.

### 1.9.38.1.17 Field: Residual Volumetric Moisture Content of the Soil Layer

The field allows for user input of the residual moisture content of the soil layer. Default is .01, range is [.01,.1].

### 1.9.38.1.18 Field: Initial Volumetric Moisture Content of the Soil Layer

The field allows for user input of the initial moisture content of the soil layer. Range is (.05, .5] with the default being .1.

### 1.9.38.1.19 Field: Moisture Diffusion Calculation Method

The field allows for two models to be selected: **Simple** or **Advanced**. EnergyPlus Currently supports only the **Simple Moisture Diffusion Calculation Method**.

**Simple** is the original Ecoroof model - based on a constant diffusion of moisture through the soil. This model starts with the soil in two layers. Every time the soil properties update is called, it will look at the two soils moisture layers and asses which layer has more moisture in it. It then takes moisture from the higher moisture layer and redistributes it to the lower moisture layer at a constant rate.

**Advanced** is the later Ecoroof model. The model requires higher number of timesteps in hour for the simulation with a recommended value of 20. This moisture transport model is based on a project which looked at the way moisture transports through soil. It uses a finite difference method to divide the soil into layers (nodes). It redistributes the soil moisture according the model described in:

Marcel G Schaap and Martinus Th. van Genuchten, 2006, ‘A modified Maulem-van Genuchten Formulation for Improved Description of the Hydraulic Conductivity Near Saturation’, Vadose Zone Journal 5 (1), p 27-34. However, currently **Advanced Moisture Diffusion Calculation Method** is not supported in EnergyPlus.

### 1.9.39 Ecoroof / RoofVegetation outputs

The following outputs are available for the Roof Vegetation surface.

- Zone,Average,Green Roof Soil Temperature [C]
- Zone,Average,Green Roof Vegetation Temperature [C]
- Zone,Average,Green Roof Soil Root Moisture Ratio []
- Zone,Average,Green Roof Soil Near Surface Moisture Ratio []
- Zone,Average,Green Roof Soil Sensible Heat Transfer Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Green Roof Vegetation Sensible Heat Transfer Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Green Roof Vegetation Moisture Transfer Rate [m/s]
- Zone,Average,Green Roof Soil Moisture Transfer Rate [m/s]
- Zone,Average,Green Roof Vegetation Latent Heat Transfer Rate per Area [W/m<sup>2</sup>]
- Zone,Average,Green Roof Soil Latent Heat Transfer Rate per Area [W/m<sup>2</sup>]

- Zone,Sum,Green Roof Cumulative Precipitation Depth [m]
- Zone,Sum,Green Roof Cumulative Irrigation Depth [m]
- Zone,Sum,Green Roof Cumulative Runoff Depth [m]
- Zone,Sum,Green Roof Cumulative Evapotranspiration Depth [m]
- Zone,Sum,Green Roof Current Precipitation Depth [m]
- Zone,Sum,Green Roof Current Irrigation Depth [m]
- Zone,Sum,Green Roof Current Runoff Depth [m]
- Zone,Sum,Green Roof Current Evapotranspiration Depth [m]

### 1.9.39.1 Green Roof Soil Temperature [C]

Temperature of the Soil layer temperature in C. Note that **Surface Outside Face Temperature** of Roof, one of the surface output variables, is the temperature at the interface between the soil and the next material layer.

### 1.9.39.2 Green Roof Vegetation Temperature [C]

Temperature of the Vegetation layer temperature in C.

### 1.9.39.3 Green Roof Soil Root Moisture Ratio []

Mean value of root moisture ( $\text{m}^3/\text{m}^3$ )

### 1.9.39.4 Green Roof Soil Near Surface Moisture Ratio []

The moisture content in the soil near the surface ( $\text{m}^3/\text{m}^3$ )

### 1.9.39.5 Green Roof Soil Sensible Heat Transfer Rate per Area [W/m<sup>2</sup>]

Sensible heat flux to ground (W/m<sup>2</sup>)

### 1.9.39.6 Green Roof Vegetation Sensible Heat Transfer Rate per Area [W/m<sup>2</sup>]

Sensible heat transfer to foliage (W/m<sup>2</sup>)

### 1.9.39.7 Green Roof Vegetation Moisture Transfer Rate [m/s]

Water evapotranspiration rate associated with latent heat from vegetation (m/s)

### 1.9.39.8 Green Roof Soil Moisture Transfer Rate [m/s]

Water evapotranspiration rate associated with latent heat from ground surface (m/s)

### 1.9.39.9 Green Roof Vegetation Latent Heat Transfer Rate per Area [W/m<sup>2</sup>]

Latent heat flux from vegetation (W/m<sup>2</sup>)

**1.9.39.10 Green Roof Soil Latent Heat Transfer Rate per Area [W/m<sup>2</sup>]**

Latent heat flux from ground surface (W/m<sup>2</sup>)

**1.9.39.11 Green Roof Cumulative Precipitation Depth [m]****1.9.39.12 Green Roof Current Precipitation Depth [m]**

Cumulative or current precipitation (m)

**1.9.39.13 Green Roof Cumulative Irrigation Depth [m]****1.9.39.14 Green Roof Current Irrigation Depth [m]**

Cumulative or current irrigation (m)

**1.9.39.15 Green Roof Cumulative Runoff Depth [m]****1.9.39.16 Green Roof Current Runoff Depth [m]**

Cumulative or current runoff (m). Multiply by roof area to get volume.

**1.9.39.17 Green Roof Cumulative Evapotranspiration Depth [m]****1.9.39.18 Green Roof Current Evapotranspiration Depth [m]**

Cumulative or current evapotranspiration from soil and plants (m).

## **1.9.40 MaterialProperty:GlazingSpectralData**

With the MaterialProperty:GlazingSpectralData object, you can specify the wavelength-by-wavelength transmittance and reflectance properties of a glass material. To determine the overall optical properties of a glazing system (solar and visible transmittance and solar absorptance vs. angle of incidence) EnergyPlus first calculates transmittance and absorptance vs. angle of incidence for each wavelength. This is then weighted by a standard solar spectrum to get the solar transmittance and absorptance vs. angle of incidence (for use in the solar heat gain calculations), and further weighted by the response of the human eye to get the visible transmittance vs. angle of incidence (for use in the daylighting calculation).

MaterialProperty:GlazingSpectralData should be used for multi-pane windows when one or more of the glass layers is *spectrally selective*, i.e., the transmittance depends strongly on wavelength. An example is glass with a coating that gives high transmittance in the daylight part of the solar spectrum (roughly 0.4 to 0.7 microns) and low transmittance at longer wavelengths, thus providing better solar heat gain control than uncoated glass. If spectral data is not used in case, the overall optical properties of the glazing system that EnergyPlus calculates will not be correct.

You can input up to 450 sets of values for wavelengths covering the solar spectrum. Each set consists of {wavelength (microns), transmittance, front reflectance, back reflectance}

Spectral data of this kind are routinely measured by glass manufacturers. Data sets for over 800 commercially available products are contained in an Optical Data Library maintained by the Windows Group at Lawrence Berkeley National Laboratory. This library can be downloaded from <http://windows.lbl.gov/>. You will have to edit entries from this library to put them in the format required by the EnergyPlus WindowGlassSpectralData object.

An alternative to using the MaterialProperty:GlazingSpectralData object is to run the WINDOW window analysis program. This program has built-in access to the Optical Data Library and let's you

easily create customized, multi-layer glazing systems that can be exported for use in EnergyPlus. For more details, see “StormWindow”.

### 1.9.40.1 Inputs

#### 1.9.40.1.1 Field: Name

The name of the spectral data set. It is referenced by `WindowMaterial:Glazing` when Optical Data Type = Spectral.

#### 1.9.40.1.2 Fields 1-4 (repeated up to 450 times)

Sets of values for wavelengths covering the solar spectrum (from about 0.25 to 2.5 microns [ $10^{-6}$  m]). Each set consists of

**{wavelength (microns), transmittance, front reflectance, back reflectance}**

The wavelength values must be in ascending order. The transmittance and reflectance values are at normal incidence. “Front reflectance” is the reflectance for radiation striking the glass from the outside, i.e., from the side opposite the zone in which the window is defined. “Back reflectance” is the reflectance for radiation striking the glass from the inside, i.e., from the zone in which the window is defined. Therefore, for exterior windows, “front” is the side closest to the outdoors and “back” is the side closest to the zone in which the window is defined. For interior windows, “front” is the side closest to the adjacent zone and “back” is the side closest to the zone in which the window is defined.

An IDF example:

```

### 1.9.41 Construction

For walls, roofs, floors, windows, and doors, constructions are “built” from the included materials. Each layer of the construction is a material name listed in order from “outside” to “inside”. Up to ten layers (eight for windows) may be specified (one of the few limitations in EnergyPlus!). “Outside” is the layer furthest away from the Zone air (not necessarily the outside environment). “Inside” is the layer next to the Zone air. In the example floor below, for example, the outside layer is the acoustic tile below the floor, the next layer is the air space above the tile, and the inside layer is the concrete floor deck.

Window constructions are similarly built up from items in the Window Materials set using similar layers.. See Figure 1.27. Illustration for material ordering in windows, which shows the case where an interior shading layer such as a blind is present. The gap between the inside glass layer (layer #3) and the

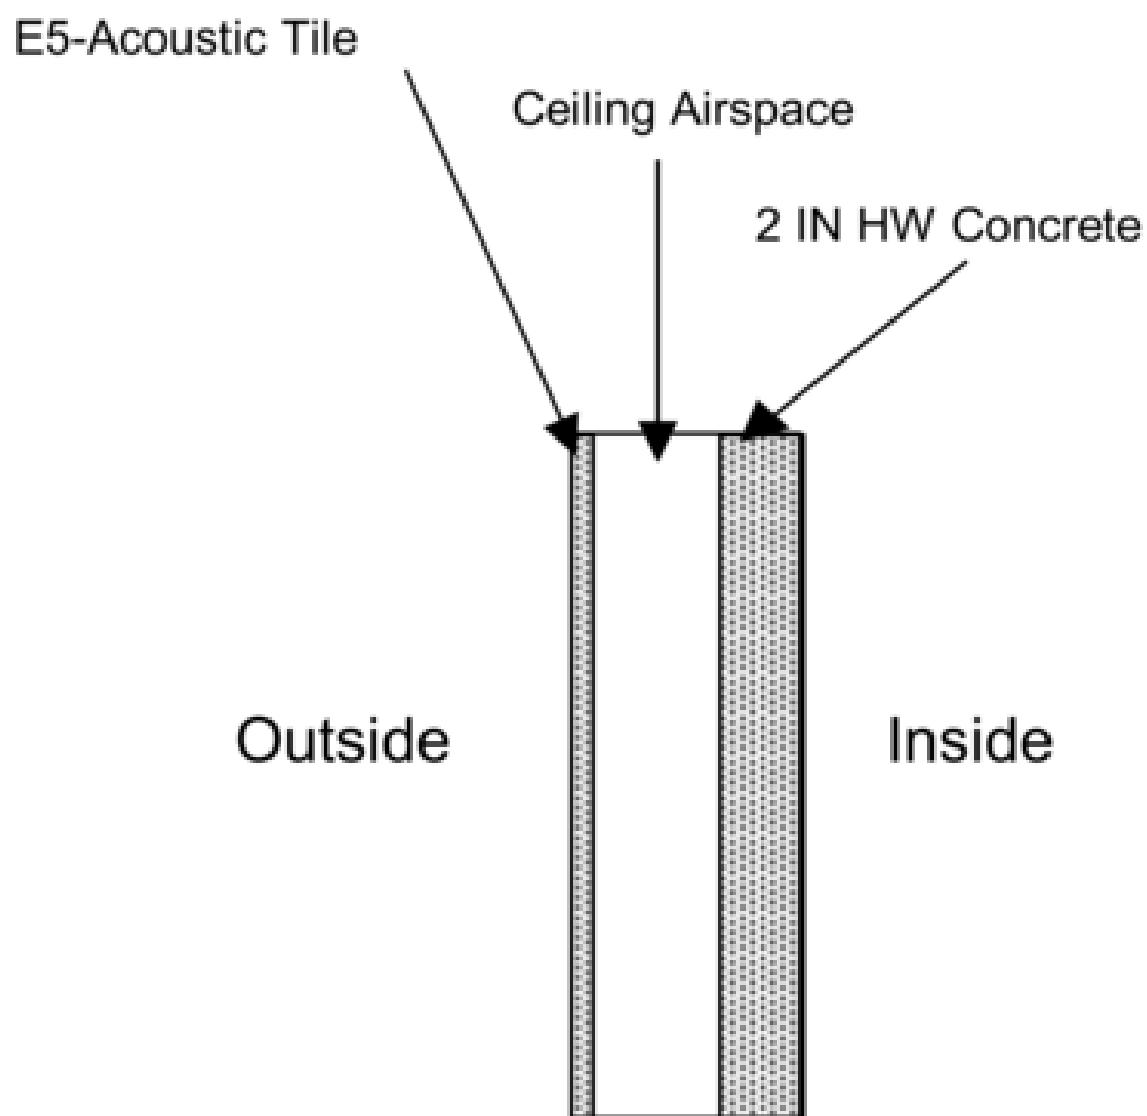

Figure 1.26: Example Floor Construction illustration.

interior shading layer is not entered. Similarly, for an exterior shading layer, the gap between the outside glass layer and the shading layer is not entered.

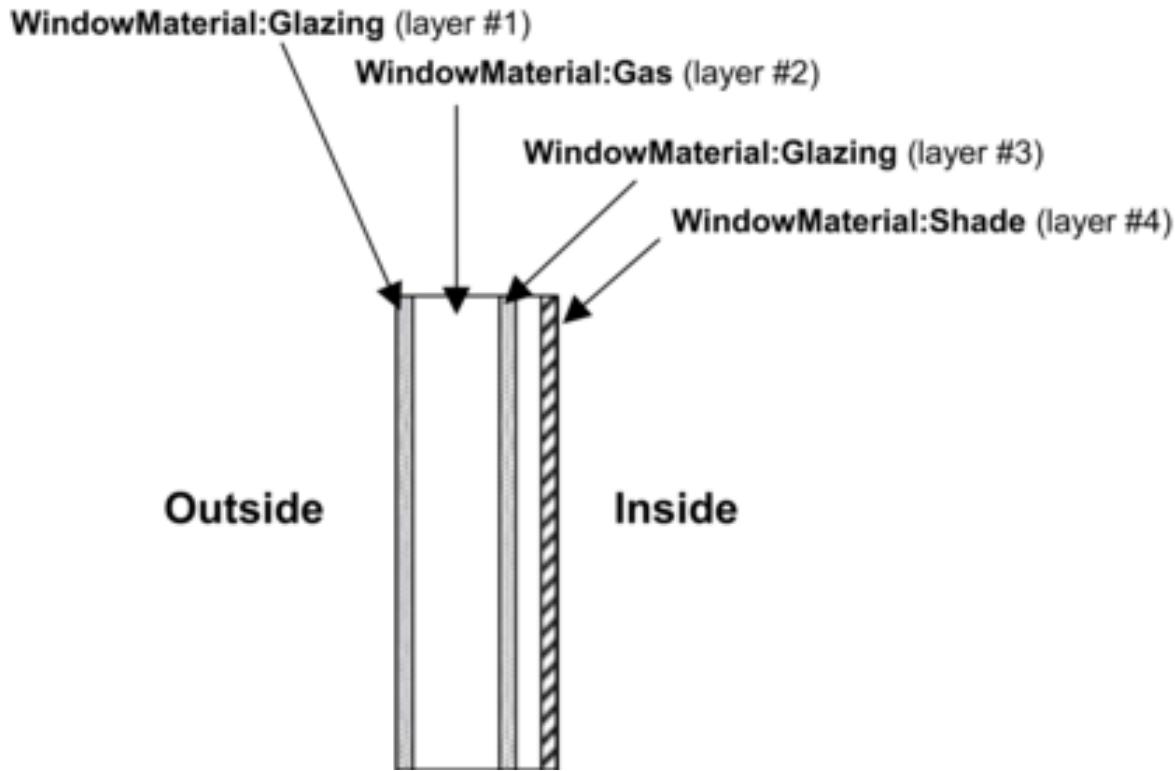

Figure 1.27: Illustration for material ordering in windows.

However, for a between-glass shading device the gaps on either side of the shading layer must be entered and they must have the same gas type. In addition, the gap widths with and without the between-glass shading layer must be consistent (see Figure 1.28).

A maximum of four glass layers and one shading layer is allowed. A gas layer must always separate adjacent glass layers in a multi-pane glazing without a between-glass shading layer.

Outside and inside air film resistances are never given as part of a construction definitions since they are calculated during the EnergyPlus simulation. Note also that constructions are assumed to be one-dimensional in a direction perpendicular to the surface.

### 1.9.41.1 Inputs

#### 1.9.41.1.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is. This name must be identical to one of the Construction definitions in the input data file.

#### 1.9.41.1.2 Field: Outside Layer

Each construction must have at least one layer. This field defines the material name associated with the layer on the outside of the construction—outside referring to the side that is not exposed to the zone but rather the opposite side environment, whether this is the outdoor environment or another zone. Material layers are defined based on their thermal properties elsewhere in the input file (ref: Material and Material Properties and Materials for Glass Windows and Doors). As noted above, the outside layer should NOT

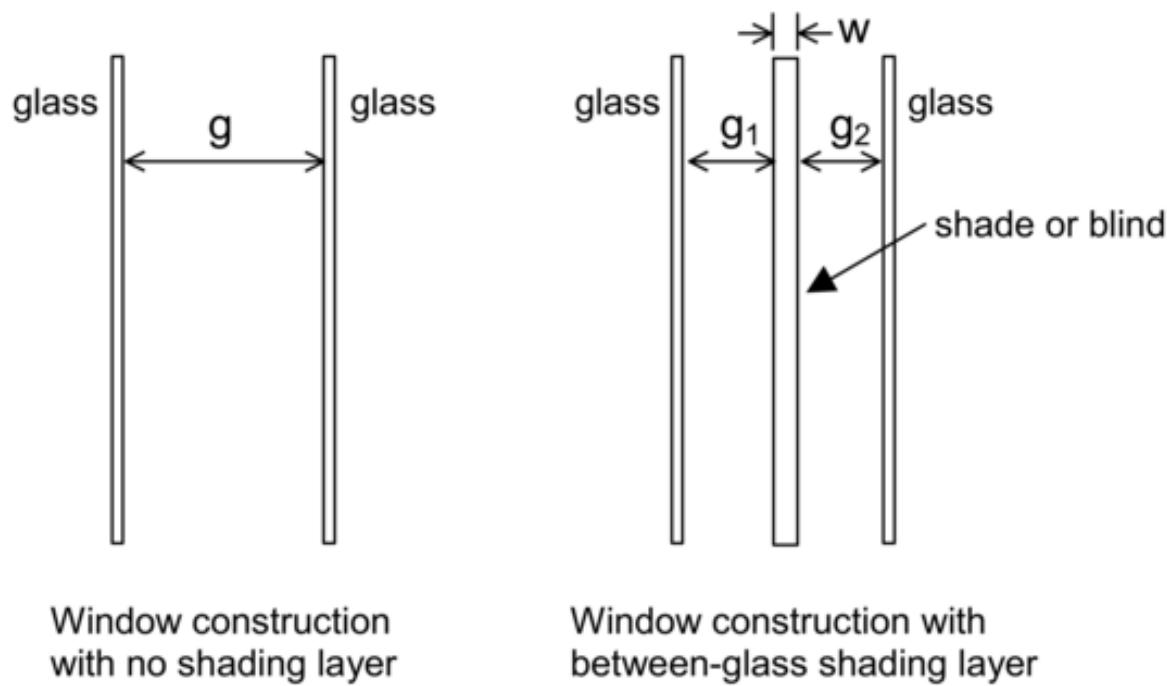

Figure 1.28: Window construction with and without a between-glass shading layer. Shown are gap widths  $g$ ,  $g_1$  and  $g_2$ , and shading layer width,  $w$ . An error will result if  $g_1 + g_2 + w$  is not equal to  $g$ , where  $w$  is zero for a blind and greater than zero for a shade.

be a film coefficient since EnergyPlus will calculate outside convection and radiation heat transfer more precisely.

#### 1.9.41.1.3 Field(s) 2-10: Layers

The next fields are optional and the number of them showing up in a particular Construction definition depends solely on the number of material layers present in that construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate inside convection and radiation heat transfer more precisely.

IDF Example (floor construction):

```
Construction, FLOOR38, ! Material layer names follow:
  E5 - ACOUSTIC TILE,
  E4 - CEILING AIRSPACE,
  C12 - 2 IN HW CONCRETE;
```

IDF Example (window construction, no shade):

```
Construction, DOUBLE PANE WINDOW, !- Material layer names follow:
  GLASS - CLEAR SHEET 1 / 8 IN,
  WinAirB1 - AIRSPACE RESISTANCE,
  GLASS - CLEAR SHEET 1 / 8 IN;
```

IDF Example (window construction, with interior shade):

```
Construction, DOUBLE PANE WITH ROLL SHADE, !- Material layer names follow:
  GLASS - CLEAR SHEET 1 / 8 IN,
  WinAirB1 - AIRSPACE RESISTANCE,
  GLASS - CLEAR SHEET 1 / 8 IN,
  ROLL SHADE - LIGHT
```

#### 1.9.42 Constructions - Modeling Underground Walls and Ground Floors Defined with C and F Factors for Building Energy Code Compliance

Building energy code and standards like ASHRAE 90.1, 90.2 and California Title 24 require the underground wall constructions and slabs-on-grade or underground floors not to exceed certain maximum values of C-factor and F-factor, which do not specify detailed layer-by-layer materials for the constructions.

A simplified approach is introduced to create equivalent constructions and model the ground heat transfer through underground walls and ground floors for the building energy code compliance calculations. The approach is to create constructions based on the user defined C or F factor with two layers: one concrete layer (0.15 m thick) with thermal mass, and one fictitious insulation layer with no thermal mass. Three new objects were created for such purpose: **Construction:CfactorUndergroundWall**, **Construction:FfactorGroundFloor**, and **Site:GroundTemperature:FCfactorMethod**. Details of the approach are described in the Engineering Reference document. The wall and floor construction objects are described in this section; the ground temperature object is described with the other ground temperature objects.

When a underground wall or ground floor surface (**BuildingSurface:Detailed**, **Floor:Detailed**, and **Wall:Detailed**) references one of the two construction objects, its field ‘Outside Boundary Condition’ needs to be set to **GroundFCfactorMethod**. For simple (rectangular) wall and floor objects, the outside boundary condition is inferred from the construction type.

The Site:GroundTemperature:FCfactorMethod is described in the section for ground temperatures, the following section describes the two new construction objects.

### 1.9.43 Construction:CfactorUndergroundWall

This input object differs from the usual wall construction object in that it describes an entire construction rather than individual layers. This object is used when only the wall height (depth to the ground) and the C-factor are available. This object accesses a model that creates an equivalent layer-by-layer construction for the underground wall to approximate the heat transfer through the wall considering the thermal mass of the earth soil.

This object is referenced by underground wall surfaces with their fields ‘Outside Boundary Condition’ set to GroundFCfactorMethod.

#### 1.9.43.1 Inputs

##### 1.9.43.1.1 Field: Name

The name of the underground wall construction.

##### 1.9.43.1.2 Field: C-Factor

C-Factor is the time rate of steady-state heat flow through unit area of the construction, induced by a unit temperature difference between the body surfaces. The C-Factor unit is W/m<sup>2</sup> · K. The C-factor does not include soil or air films. ASHRAE Standard 90.1 and California Title 24 specify maximum C-factors for underground walls depending on space types and climate zones.

##### 1.9.43.1.3 Field: Height

This field describes the height of the underground wall, i.e. the depth to the ground surface. The unit is meters.

IDF Example:

```
Construction:CfactorUndergroundWall,
  CfactorUGWall,
  0.436,           ! C-factor (W/m2K), does not include soil or air films
  4.57;           ! Height (m)

BuildingSurface:Detailed,
  Zn001:Wall1001,      !- Name
  Wall,                !- Surface Type
  CfactorUGWall,       !- Construction Name
  ZONE ONE,            !- Zone Name
  GroundFCfactorMethod, !- Outside Boundary Condition
  ,                   !- Outside Boundary Condition Object
  NoSun,               !- Sun Exposure
  NoWind,               !- Wind Exposure
  0.0,                 !- View Factor to Ground
  4,                  !- Number of Vertices
  0.0,0.0,4.572,       !- X,Y,Z = > Vertex 1
  0.0,0.0,0.0,         !- X,Y,Z = > Vertex 2
  15.24,0.0,0.0,       !- X,Y,Z = > Vertex 3
  15.24,0.0,4.572;    !- X,Y,Z = > Vertex 4
```

### 1.9.44 Construction:FfactorGroundFloor

This input object differs from the usual ground floor construction object in that it describes an entire construction rather than individual layers. This object is used when only the floor area, exposed perimeter,

and the F-factor are available. This object accesses a model that creates an equivalent layer-by-layer construction for the slab-on-grade or underground floor to approximate the heat transfer through the floor considering the thermal mass of the earth soil.

This object is referenced by slab-on-grade or underground floor surfaces with their fields ‘Outside Boundary Condition’ set to GroundFCfactorMethod.

### 1.9.44.1 Inputs

#### 1.9.44.1.1 Field: Name

The name of the ground floor construction.

#### 1.9.44.1.2 Field: F-Factor

F-Factor represents the heat transfer through the floor, induced by a unit temperature difference between the outside and inside air temperature, on the per linear length of the exposed perimeter of the floor. The unit for this input is W/m · K. ASHRAE Standard 90.1 and California Title 24 specify maximum F-factors for slab-on-grade or underground floors depending on space types and climate zones.

#### 1.9.44.1.3 Field: Area

This field describes the area (in square meters) of the slab-on-grade or underground floor.

#### 1.9.44.1.4 Field: PerimeterExposed

This field describes the exposed (direct contact with ambient air) perimeter (in meters) of the slab-on-grade or underground floor.

IDF Example:

```
Construction:FfactorGroundFloor,
  slabconst,
  0.12,      !F-factor in W/m-K
  232.26,    !Area in m2
  61.0;      !Exposed perimeter in m

BuildingSurface:Detailed,
  Zn001:Flr001,           !- Name
  Floor,                  !- Surface Type
  slabconst,              !- Construction Name, FLOOR
  ZONE ONE,               !- Zone Name
  GroundFCfactorMethod,   !- Outside Boundary Condition, Surface
  ,                      !- Outside Boundary Condition Object, Zn001:Flr001
  NoSun,                 !- Sun Exposure
  NoWind,                !- Wind Exposure
  0,                     !- View Factor to Ground
  4,                     !- Number of Vertices
  15.24,0.0,0.0,          !- X,Y,Z = > Vertex 1
  0.0,0.0,0.0,            !- X,Y,Z = > Vertex 2
  0.0,15.240,0.0,         !- X,Y,Z = > Vertex 3
  15.24,15.24,0.0;       !- X,Y,Z = > Vertex 4
```

### 1.9.45 ConstructionProperty:InternalHeatSource

In some cases, such as radiant systems, a construction will actually have resistance wires or hydronic tubing embedded within the construction. Heat is then either added or removed from this building element to provide heating or cooling to the zone in question. In the case of building-integrated photovoltaics, the energy removed in the form of electricity will form a sink. It is possible to enter such constructions into EnergyPlus with the syntax described below. The internal source capability is available with both

the **ConductionTransferFunction** and **ConductionFiniteDifference** solution algorithms. The only difference is that the two dimensional pipe arrangements are not available to ConductionFiniteDifference. Those fields are ignored in that implementation.

### 1.9.45.1 Inputs

#### 1.9.45.1.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is.

#### 1.9.45.1.2 Field: Source Present After Layer Number

This field is an integer that relates the location of the heat source or sink. The integer refers to the list of material layers that follow later in the syntax and determines the layer after which the source is present. If a source is embedded within a single homogenous layer (such as concrete), that layer should be split into two layers and the source added between them. For example, a value of “2” in this field tells EnergyPlus that the source is located between the second and third material layers listed later in the construction description (see layer fields below). This field must be between 1 and the number of material layers in the construction (maximum of 10 layers).

#### 1.9.45.1.3 Field: Temperature Calculation Requested After Layer Number

The nature of this field is similar to the source interface parameter (see previous field) in that it is an integer, refers to the list of material layers that follow, and defines a location after the layer number identified by the user-defined number. In this case, the user is specifying the location for a separate temperature calculation rather than the location of the heat source/sink. This feature is intended to allow users to calculate a temperature within the construction. This might be important in a radiant cooling system where condensation could be a problem. This temperature calculation can assist users in making that determination in absence of a full heat and mass balance calculation. This field must be between 1 and the number of material layers in the construction (maximum of 10 layers).

It should also be noted that when using this construction in conjunction with a low temperature radiant system such as the **variable flow**, **constant flow**, or **electric** radiant system that this parameter also defines the location for the temperature that is used with the Surface Interior Temperature control. In other words, when using the Surface Interior Temperature control with a low temperature radiant system, the location for this temperature that is interior to the radiant surface is also defined in part by this input field. Note that two fields below (**Dimensions for the CTF Calculation** and **Two-Dimensional Temperature Calculation Position**) will also have an impact on this location if the user elects to perform a 2-D solution for the surfaces using this construction.

#### 1.9.45.1.4 Field: Dimensions for the CTF Calculation

This field is also an integer and refers to the detail level of the calculation. A value of “1” states that the user is only interested in a one-dimensional calculation. This is appropriate for electric resistance heating and for hydronic heating (when boiler/hot water heater performance is not affected by return and supply water temperatures). A value of “2” will trigger a two-dimensional solution for this surface only. This may be necessary for hydronic radiant cooling situations since chiller performance is affected by the water temperatures provided.

A few things should be noted about requesting two-dimensional solutions. First, the calculation of the conduction transfer functions (CTF) is fairly intensive and will require a significant amount of computing time. Second, the solution regime is two-dimensional internally but it has a one-dimensional boundary

condition imposed at the inside and outside surface (i.e., surface temperatures are still isothermal as if the surface was one-dimensional).

#### 1.9.45.1.5 Field: Tube Spacing

This field defines the distance between adjacent hydronic tubes spaced in the direction perpendicular to the main direction of heat transfer. The value for this parameter must be greater than 0.01m (or a tube spacing of 1 cm) and less than 1.0m (or a tube spacing of 1m). Note that this parameter is only used for two-dimensional solutions (see previous field) or when the user requests that the tube length for a hydronic radiant system (**variable flow** or **constant flow**) be autosized. In the case of autosizing the tube length, this parameter is used along with the dimensions of the surface to approximate the tube length.

#### 1.9.45.1.6 Field: Two-Dimensional Temperature Calculation Position

This field only has a meaning when the user opts to have a two-dimensional solution in **Dimensions for the CTF Calculation** above. It is used in conjunction with the information in **Temperature Calculation Requested After Layer Number** above to specify a location for where the simulation will calculate a temperature at the interior of a surface. The **Temperature Calculation Requested After Layer Number** field sets where the position is in the main direction of heat transfer. This field determines the position of this point in the direction **perpendicular** to the main direction of heat transfer. Note that this parameter is a dimensionless value that is allowed to range from 0.0 to 1.0. A value of 0.0 is used for a position that is in line with the tubing in the construction. A value of 1.0 is used for a position that is at the mid-point between adjacent tubes. The user is also given the flexibility to select a point in between those two extremes.

It should also be noted that for values between 0.0 and 1.0 will not allow for exact positioning of the point at which this temperature is calculated. Instead, it will be used to calculate which node in the state space representation will be used to calculate the temperature. Currently, EnergyPlus uses seven nodes in the direction perpendicular to the main direction of heat transfer. In this case, 0.0 represents the first node and 1.0 represents the seventh or last node in the perpendicular direction. So, this field will be used to determine which node in the direction perpendicular to the main direction of heat transfer to use and there are five other nodes (second, third, fourth, fifth, and sixth) that are possible locations. For example, if the user enters a value of 0.167, the second node will be used. Likewise, if the user enters a value of 0.1, because this will be closest to the second node, the second node will be used to calculate the internal temperature. For more information on two-dimensional heat transfer within surfaces using ConstructionProperty:InternalHeatSource, please refer to the EnergyPlus Engineering Reference.

#### 1.9.45.2 Outputs

- Zone,Average,Surface Internal Source Location Temperature [C]
- Zone,Average,Surface Internal User Specified Location Temperature [C]
- Zone,Average,CondFD Internal Heat Source Power After Layer N [W]
- Zone,Average,CondFD Internal Heat Source Energy After Layer N [J]

##### 1.9.45.2.1 Surface Internal Source Location Temperature [C]

This output is the temperature within the surface at the location of the source/sink.

##### 1.9.45.2.2 Surface Internal User Specified Location Temperature [C]

This output is the temperature within the surface at the location requested by the user.

### 1.9.45.2.3 CondFD Internal Heat Source Power After Layer

This output is the heat power added after material layer N from the [ConstructionProperty:InternalHeatSource](#) object. Only valid for the CondFD solution algorithm.

### 1.9.45.2.4 CondFD Internal Heat Source Energy After Layer

This output is the heat energy added after material layer N from the [ConstructionProperty:InternalHeatSource](#) object. Only valid for the CondFD solution algorithm.

### 1.9.45.2.5 CondFD EMS Heat Source Power After Layer

This output is the heat power added after material layer N from the EMS heat flux actuator (Component type: “CondFD Surface Material Layer”; Control type: “Heat Flux”). Only valid for the CondFD solution algorithm.

### 1.9.45.2.6 CondFD EMS Heat Source Energy After Layer

This output is the heat energy added after material layer N from the EMS heat flux actuator (Component type: “CondFD Surface Material Layer”; Control type: “Heat Flux”). Energy is aggregated on the electricity meter and is only valid for the CondFD solution algorithm.

## 1.9.46 Construction:AirBoundary

[Construction:AirBoundary](#) indicates an open boundary between two zones. It may be used for base surfaces and fenestration surfaces. When this construction type is used, the Outside Boundary Condition of the surface (or the base surface of a fenestration surface) must be either *Surface* or *Zone*. A base surface with [Construction:AirBoundary](#) cannot hold any fenestration surfaces.

The two zones separated by this air boundary will be grouped together into a combined enclosure for solar distribution, daylighting, and radiant exchange (including distribution of radiant internal gains). If a given zone has an air boundary with more than one zone, then all of the connected zones will be grouped together. For example, if there is an air boundary between zones A and B, and another air boundary between zones B and C, all three zones (A, B, and C) will be grouped into a single enclosure. Normal default simplified view factors will apply unless detailed view factors are specified using [ZoneProperty:UserViewFactors:BySurfaceName](#).

### 1.9.46.1 Inputs

#### 1.9.46.1.1 Field: Name

The name of the construction.

#### 1.9.46.1.2 Field: Air Exchange Method

This field controls how the surface is modeled for radiant exchange calculations. There are two choices:

**None** There will be no air exchange modeled across this surface. Other objects, such as [ZoneMixing](#) and [ZoneCrossMixing](#) or [AirflowNetwork](#) openings may be specified if desired.

**SimpleMixing** For each pair of zones connected by [Construction:AirBoundary](#), a pair of [ZoneMixing](#) objects will created automatically. These mixing objects may be automatically adjusted to balance HVAC system flows using the [ZoneAirMassFlowConservation](#) object.

### 1.9.46.1.3 Field: Simple Mixing Air Changes per Hour

If the Air Exchange Method is *SimpleMixing*\* then this field specifies the air change rate [1/hr] using the volume of the smaller zone as the basis. The default is 0.5. If an AirflowNetwork simulation is active this field is ignored.

### 1.9.46.1.4 Field:Simple Mixing Schedule Name

If the Air Exchange Method is *SimpleMixing* then this field specifies the schedule name for the air mixing across this boundary. If this field is blank, then the schedule defaults to always 1.0. If an AirflowNetwork simulation is active this field is ignored.

IDF Example:

```
Construction:AirBoundary,
  Air Wall,           !- Name
  SimpleMixing,       !- Air Exchange Method
  0.5,                !- Simple Mixing Air Changes per Hour {1/hr}
;                      !- Simple Mixing Schedule Name
```

---

## 1.9.47 Composite Wall Constructions

Standard constructions in EnergyPlus are built with the materials and layers described earlier. However, some configurations will not be adequately represented by using this approach. The Reference Data Set CompositeWallConstructions.idf contains constructions and associated materials for a set of **composite** walls. These are walls—such as stud walls—that have complicated heat-flow paths so that the conduction is two- or three-dimensional. Thermal bridges are one of the common terms for these complicated heat-flow paths; this dataset will help you represent these in EnergyPlus.

The materials here are **not** real materials but are “equivalent” materials obtained from finite-difference modeling. (The thickness, conductivity, density and specific heat values of the material layers for the different constructions have been taken from the ASHRAE report “Modeling Two- and Three-Dimensional Heat Transfer through Composite Wall and Roof Assemblies in Hourly Energy Simulation Programs (1145-TRP),” by Enermodal Engineering Limited, Oak Ridge National Laboratory, and the Polish Academy of Sciences, January 2001.). EnergyPlus will calculate conduction transfer functions using these materials. The heat transfer based on these conduction transfer functions will then be very close to what would be calculated with a two- or three-dimensional heat transfer calculation.

For stud walls, using these composite constructions will give more accurate heat flow than you would get by manually dividing the wall into a stud section and a non-stud section.

If your wall’s exterior or interior roughness or thermal, solar or visible absorptances are different from those in the data set, you can make the appropriate changes to the first material (the outside layer) or the third material (the inside layer). **None of the other values should be changed.**

Complete description of the CompositeWallConstructions data set are found in the OutputDetailsAndExamples document.

## 1.9.48 Construction:ComplexFenestrationState

This input object is used to describe the properties of a single state for complex fenestration. There are two parts to the input, 1) layer-by-layer physical description of fenestration system and 2) a set of matrices that describe overall system optical performance. Each layer also has associated with it two matrices that give the layer absorptance (for front and back incidence on the system).

The optical properties are given as a two-dimensional matrix describing the basis and four two-dimensional matrices of system bidirectional optical properties.

These input objects will generally be exported directly from the WINDOW program and it is expected that users usually will not develop the input themselves. However, this is an option for users who prefer to use a different method (e.g., Monte-Carlo ray-trace or measurement) of determining optical properties.

Multiple instances of this object are used to define the separate operating states of complex fenestration. For example, blinds could be deployed or redirected to create a new state, or electrochromic glazings could change transmittance. Each separate state defines the materials present and the overall optical performance. If the glazing system has only one state, then only one of these objects is needed.

If there is more than one complex fenestration state, it will be controlled using the EMS actuator called “Surface” with the control type “Construction State” and the EMS input object called [EnergyManagementSystem:ConstructionIndexVariable](#).

### **1.9.48.1 Inputs**

#### **1.9.48.1.1 Field: Name**

Unique name of this construction. Used to identify type of window in surface objects.

#### **1.9.48.1.2 Field: Basis Type keyword**

Only value currently implemented is “LBNLWINDOW”. More options may be added in the future.

#### **1.9.48.1.3 Field: Basis Symmetry, keyword**

Only value currently implemented is “None”. More options will be added in the future.

#### **1.9.48.1.4 Field: Thermal Parameters**

This field gives the name of [WindowThermalModel:Params](#) object used to keep common data necessary for thermal simulation.

#### **1.9.48.1.5 Field: Basis Matrix Name**

This field gives the name of an  $2 \times N$  matrix object that defines the basis. For a fenestration basis,  $N$  would be the number of theta (polar angle) values, the first of the two elements for each of the  $i = 1,..,N$  would be the theta value, and the second would be the number of phi (azimuthal angle) values that  $360^\circ$  is divided into for that theta.

#### **1.9.48.1.6 Field: Solar Optical Complex Front Transmittance Matrix Name**

This field contains the name of matrix object that describes the solar transmittance at different incident angles. This is from the outside toward the inside.

#### **1.9.48.1.7 Field: Solar Optical Complex Back Reflectance Matrix Name**

This field contains the name of matrix object that describes the solar back reflectance at different incident angles. This is from the inside toward the outside.

#### **1.9.48.1.8 Field: Visible Optical Complex Front Transmittance Matrix Name**

This field contains the name of matrix object that describes the visible transmittance at different incident angles. This is from the outside toward the inside.

#### **1.9.48.1.9 Field: Visible Optical Complex Back Reflectance Matrix Name**

This field contains the name of vector object that describes the visible back reflectance at different incident angles. This is from the inside toward the outside.

### 1.9.48.1.10 Field: Outside Layer <x = 1>

Each construction must have at least one layer. The layer order is from outside to inside, with the first layer being either `WindowMaterial:Glazing` or `WindowMaterial:ComplexShade`. The next layer is a `WindowMaterial:Gap` layer, and the following layers then alternate between `WindowMaterial:Glazing` or `WindowMaterial:ComplexShade` and `WindowMaterial:Gap`. The last layer cannot be `WindowMaterial:Gap`.

### 1.9.48.1.11 Field: Outside Layer Directional Front Absorptance Matrix Name

Points to an Nbasis x 1 matrix object.

### 1.9.48.1.12 Field: Outside Layer Directional Back Absorptance Matrix Name

Points to an Nbasis x 1 matrix object.

### 1.9.48.1.13 Above 3 fields are optionally repeated for layers 2-10

These layers include gaps, which do not need to have matrix data specified.

An IDF example of complex fenestration with single layer:

```
Construction:ComplexFenestrationState,      !- single layer example
CFS_Glz_1,                                !- name
LBNLWindow,                               !- basis type
None,                                     !- basis symmetry type
ThermParam_1,                             !- window thermal model
CFS_Glz_1_Basis,                           !- basis matrix name
CFS_Glz_1_TfSol,                           !- TfSol
CFS_Glz_1_RbSol,                           !- Rbsol
CFS_Glz_1_Tfvis,                           !- Tfvis
CFS_Glz_1_Tbvis,                           !- Tbvis
Glass_102_Layer,                           !- layer 1 name
CFS_Glz_1_Layer_1_fAbs,                   !- fAbs
CFS_Glz_1_Layer_1_bAbs;                  !- bAbs
```

An complex fenestration IDF example with double layer (first layer is shading device):

```
Construction:ComplexFenestrationState,      !- double layer example
CFS_Glz_59,                                !- name
LBNLWindow,                               !- basis type
None,                                     !- basis symmetry type
ThermParam_59,                            !- window thermal model
CFS_Glz_59_Basis,                          !- basis matrix name
CFS_Glz_59_TfSol,                           !- TfSol
CFS_Glz_59_RbSol,                           !- Rbsol
CFS_Glz_59_Tfvis,                           !- Tfvis
CFS_Glz_59_Tbvis,                           !- Tbvis
Shade_30001_Layer,                         !- layer 1 name (shading device)
CFS_Glz_59_Layer_1_fAbs,                   !- fAbs
CFS_Glz_59_Layer_1_bAbs,                   !- bAbs
Gap_1_Layer,                               !- layer 1 name
,                                         !- absorptance matrices for gaps should be empty for now
,                                         !- it is for future use
Glass_3110_Layer,                           !- layer 2 name
CFS_Glz_59_Layer_3110_fAbs,                 !- fAbs
CFS_Glz_59_Layer_3110_bAbs;                !- bAbs
```

## 1.9.49 WindowThermalModel:Params

This input object is used with the `Construction:ComplexFenestrationState`

### 1.9.49.1 Inputs

#### 1.9.49.1.1 Field: Name

Unique name of the window thermal model parameters.

#### 1.9.49.1.2 Field: Calculation Standard

The type of the calculation standard. The choices are:

- ISO15099
- EN673Declared
- EN673Design

The default is ISO15099.

#### 1.9.49.1.3 Field: Thermal Model

The type of thermal model. The choices are:

- ISO15099
- ScaledCavityWidth
- ConvectiveScalarModel\_NoSDThickness
- ConvectiveScalarModel\_withSDThickness

The default is ISO15099.

#### 1.9.49.1.4 Field: SD Scalar

Shading Device Scalar Factor. Only used for Thermal Model = Convective Scalar Model. Factor of venetian shading device layer contribution to convection. Real value between 0 (where the shading device contribution to convection is neglected) and 1 (where the shading device treated as “closed” – as if it is a glass layer with thermal properties of SD slat material). Default: 1.0

#### 1.9.49.1.5 Field: Deflection Model

The type of deflection model used to model deflection in windows and glass. The choices are:

- NoDeflection
- TemperatureAndPressureInput
- MeasuredDeflection

The default is NoDeflection.

#### 1.9.49.1.6 Field: Vacuum Pressure Limit

The pressure (Pa) which will be considered to be the limit for vacuum glazing pressure. All pressures less than or equal to this pressure will be considered to be vacuum. Default: 13.238 Pa.

#### 1.9.49.1.7 Field: Initial Temperature

The temperature ( $^{\circ}\text{C}$ ) of the gap in the time of fabrication. It is used only when WindowThermalModel:Params DeflectionModel = TemperatureAndPressureInput

### 1.9.49.1.8 Field: Initial Pressure

The pressure (Pa) of the gap at the time of fabrication of the sealed glazing system unitIt is used only when WindowThermalModel:Params DeflectionModel = TemperatureAndPressureInput.

An IDF example for WindowThermalModel:Params (without deflection):

```
WindowThermalModel:Params ,
  ThermParam_59,
  ISO15099,
  ISO15099,
  1.00,
  NoDeflection;
```

---

An IDF example for thermal parameters (with deflection):

```
WindowThermalModel:Params ,
  ThermParam_59,
  ISO15099,
  ISO15099,
  1.00,
  TemperatureAndPressureInput,
  ,
  21.00,
  10000.00;
```

---

An IDF example for WindowThermalModel:Params for modeling vacuum glazing

```
WindowThermalModel:Params ,
  ThermParam_1006,
  ISO15099,
  ISO15099,
  1.0000,
  NoDeflection,
  13.238;
```

---

## 1.9.50 Matrix:TwoDimension

This is input object is only used with **Construction:ComplexFenestrationState** object to enter a two-dimensional matrix of values.

It is used to define the Basis Matrix for BSDF input data, and is also used to define the actual BSDF matrices data for the complete fenestration definition as well as the individual layers of the system.

The data are entered in row-major order: all the elements of row 1, followed by all the elements of row 2, etc. The number of values to be entered depends on the number of rows and the number of columns. Blank fields are treated as having been set to zero.

See example IDF file “SmOff\_CmplxGlz\_IntExtShading.idf” for the definition of two complex shading layers with matrix data defined.

### 1.9.50.1 Field: Name

Unique name of matrix input object.

### 1.9.50.2 Field: Number of Rows

This field is the number of rows in the matrix.

### 1.9.50.3 Field: Number of Columns

This field is the number of columns in the matrix

#### 1.9.50.4 < Field Set: Value # N >

Repeat entering value exactly the same number of times as the number of rows times the number of columns.

#### 1.9.50.5 Field: Value # 1

This is the value of the matrix at the first row and first column.

#### 1.9.50.6 Field: Value #2

This is the value of the matrix at the first row and the second column.

An IDF example of matrix for defining BSDF basis:

```
Matrix:TwoDimension,      !- matrix for basis definition
CFS_Glz_1_Basis,         !- basis matrix name
9,                      !- number of rows
2,                      !- number of columns
0.00000, 1.00000,
10.00000, 8.00000,
20.00000, 16.00000,
30.00000, 20.00000,
40.00000, 24.00000,
50.00000, 24.00000,
60.00000, 24.00000,
70.00000, 16.00000,
82.50000, 12.00000;
```

### 1.9.51 Construction:WindowEquivalentLayer

This object defines the construction for equivalent layer window (ASHWAT) model. This window can model various mix of glazing and shading layers combination. Shadings are defined as an integral part of the construction. The construction is defined by listing the layers name starting with outside layer and work your way to the inside Layer. Up to six solid layers (glazing and shade) and up to five gaps, i.e., a total of up to 11 layers maximum are allowed in equivalent layer window object. The solid layer types allowed are: Glazing, Insect Screen, Roller Blinds, Venetian Blind, and Drape Fabrics. This window model requires optical data of the individual glazing and shading layers to calculate the effective optical properties of the composite fenestration construction. Venetian blinds in equivalent layer window model can be in a fixed slat angle or has the option to control the slat angle in order to maximize visibility, or maximize solar gains. An equivalent-layer concept can simulate wide range of multiple glazing and shading layers combination and provides unlimited flexibility to combine different types of shading layers in a fenestration. The equivalent-layer window model does not support daylighting control. For the gap layer object any one of the five different Gas types can be specified: AIR, ARGON, XENON, KRYPTON, or CUSTOM. This window object is referenced by fenestration surfaces. For details of the model description refer to Equivalent Layer Fenestration Model section in Engineering Reference. The various layer objects that can be referenced in Equivalent Layer window model are:

```
WindowMaterial:Glass:EquivalentLayer
WindowMaterial:Shade:EquivalentLayer
WindowMaterial:Drape:EquivalentLayer
WindowMaterial:Blind:EquivalentLayer
WindowMaterial:Screen:EquivalentLayer
WindowMaterial:Gap:EquivalentLayer
```

### 1.9.51.1 Inputs

#### 1.9.51.1.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Fenestration) requires a construction name to define what the make-up of the fenestration is. This name must be identical to one of the Window Construction Equivalent Layer definitions in the input data file.

#### 1.9.51.1.2 Field: Outside Layer

Each equivalent layer window construction must have at least one layer. This field defines the material name associated with the layer on the outside of the construction—outside referring to the side that is exposed to the outdoor environment or another zone. Material layers for equivalent layer window model are defined based on their thermal properties elsewhere in the input file (ref: WindowEquivalentLayerMaterialNames)

#### 1.9.51.1.3 Field: Layer 2 - Layer11

The next fields are optional and the number of them showing up in a particular equivalent layer window construction definition depends solely on the number of material layers present in that construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate inside convection and radiation heat transfer more precisely.

An IDF example for this object, is shown below:

```
Construction:WindowEquivalentLayer,
  Six Solid Layers Window,      !- Name
  INSCRN,                      !- Outside Layer
  Air GAP Outdoor 12.7mm,       !- Layer 2
  GLZGRY,                      !- Layer 3
  Argon GAP Sealed 12.7mm,     !- Layer 4
  FEP,                          !- Layer 5
  Xenon GAP Sealed 12.7mm,    !- Layer 6
  LOF1436,                     !- Layer 7
  Krypton GAP Sealed 12.7mm,   !- Layer 8
  GLZCLR,                      !- Layer 9
  Air GAP Indoor 12.7mm,       !- Layer 10
  ShadeTrns;                  !- Layer 11
```

### 1.9.52 Construction:WindowDataFile

The WINDOW program, which does a thermal and optical analysis of a window under different design conditions, writes a data file (“Window data file”) containing a description of the window that was analyzed. The Construction:WindowDataFile object allows a window to be read in from the WINDOW data file—see “Importing Windows from WINDOW.” For information on adding a shading device to the window see “[WindowShadingControl](#).”

### 1.9.52.1 Inputs

#### 1.9.52.1.1 Field: Name

This is the name of a window on the Window data file. An error will result if EnergyPlus cannot find a window of this name on the file, or if the file, shown in the next field, is not present. The location of the data file should be specified in the File Name field. For details on what is done with the data if a matching window is found on the file see “Importing Windows from WINDOW.”

### 1.9.52.1.2 Field: File Name

This is the file name of the Window data file that contains the Window referenced in the previous field. The field may include a full path with file name, for precise results. The field must be < = 100 characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

If this field is left blank, the file name is defaulted to Window5DataFile.dat.

Input Example

```
Construction:WindowDataFile,
  DoubleClear;          !- Name of a Window on the Window Data File
  ! Note -- Window5DataFile.dat is presumed to be in the "run" folder where EnergyPlus.exe is

FenestrationSurface:Detailed,
  Zn001:Wall001:Win001, !- Name
  Window,                !- Class
  DoubleClear,           !- Construction Name
  Zn001:Wall001,         !- Base Surface Name, and Target (if applicable)
  0.5,                  !- View Factor to Ground
  ,                     !- Frame/Divider name
  1.0,                  !- Multiplier
  4,                   !- Number of vertices
  0.548, 0.0, 2.5000,   !- X,Y,Z of Vertices
  0.548, 0.0, 0.5000,
  5.548, 0.0, 0.5000,
  5.548, 0.0, 2.5000;
```

An example showing use of specific data file name and complete path location follows:

```
Construction:WindowDataFile,
  DoubleClear,          !- Name of a Window on the Window Data File
  C:\EnergyPlusData\DataSet\MyWindow.dat;
```

### 1.9.52.2 Outputs

An optional report (contained in **eplusout.eio**) gives calculational elements for the materials and constructions used in the input. These reports are explained fully in the Output Details and Examples document.

## 1.10 Group – Thermal Zone Description/Geometry

Without spaces, thermal zones, and surfaces, the building can't be simulated. This group of objects (Space, Zone, BuildingSurface) describes the thermal zone characteristics as well as the details of each surface to be modeled. Included here are shading surfaces.

### 1.10.1 Space

This object defines a space (or room) in the building. All Spaces are part of a **Zone**. Every Zone contains one or more spaces.

Space is an optional input. If a Zone has no Space(s) specified in the input then a default Space named <Zone Name> will be created. If some surfaces in a Zone are assigned to a Space and some are not, then a default Space named <Zone Name>-Remainder will be created. Input references to Space Names must have a matching Space object. Default space names may not be referenced in the input except for **Output:Variable** keys).

Space geometry is specified by attaching surfaces to a space using the “Space Name” field. If a Space has only floor surface(s) and internal mass assigned to it, the Space is assumed to share the same enclosure with other such Spaces in the same Zone (and with any surfaces that are not explicitly assigned to a space). If a Space also has other types of surfaces (e.g. wall, ceiling, or roof) then the Space forms its own enclosure unless it is connected to other spaces with air boundaries (see [Construction:AirBoundary](#)).

### 1.10.1.1 Inputs

#### 1.10.1.1.1 Field: Name

The name of the Space object. This name must be unique across Zone, Space, ZoneList, and SpaceList names.

#### 1.10.1.1.2 Field: Zone Name

The name of the [Zone](#) this Space is a part of. This field is required.

#### 1.10.1.1.3 Field: Floor Area

Space floor area is used in many places within EnergyPlus. EnergyPlus automatically calculates the space floor area ( $m^2$ ) as the total area of surfaces with Surface Type = Floor. If this field is 0.0, negative or **autocalculate** (the default), then the calculated space floor area will be used in subsequent calculations. If this field is positive, then it will be used as the space floor area. If the calculated floor area differs from the user input floor area by more than 5%, a warning message will be issued.

For each Zone, the calculated floor area is the sum of the space floor areas belonging to the zone. If the input for [Zone Floor Area](#) does not equal the calculated floor area, the input zone floor area will take precedence, and the space floor areas will be adjusted proportionately. If the calculated floor area differs from the user input floor area by more than 5%, a warning message will be issued.

#### 1.10.1.1.4 Field: Space Type

Space type is used to categorize spaces by activity type, such as office, classroom, storage, etc. There is no predefined list of space types; any valid input string may be used. Several table outputs include a subtable by Space Type. There are also SpaceType [Output:Meters](#). See the meter details (mtd) output file for a list of all available meters for a given simulation. If left blank, this field defaults to “General”.

#### 1.10.1.1.5 Field: Tag <#>

Tags are used to group spaces by additional characteristics that may be more or less detailed than Space Type. For example, codes and standards designations for ventilation or occupancy may use specific terms that are different from one standard to the next. There is no predefined list of tags; any valid input string may be used. Several table outputs include a subtable by Space Tag.

### 1.10.2 SpaceList

The SpaceList object defines a list of Space objects. It is primarily used with [Internal Gains](#) objects (People, Lights, etc.) to apply the same gain across a group of Spaces.

Space lists are not exclusive. A Space can be referenced by more than one SpaceList object.

### 1.10.2.1 Inputs

#### 1.10.2.1.1 Field: Name

The name of the SpaceList object. This name must be unique across Zone, Space, ZoneList, and SpaceList names.

### 1.10.2.1.2 Field: Space <#> Name

Reference to a Space object.

```
SpaceList,
  Mid Floor List,    !- Name
  Mid West Space,   !- Space 1 Name
  Mid Center Space, !- Space 2 Name
  Mid East Space;   !- Space 3 Name
```

## 1.10.3 Zone

This element sets up the parameters to simulate each thermal zone of the building. This object defines a thermal zone of the building. Every Zone contains one or more **Spaces**.

Space is an optional input. If a Zone has no Space(s) specified in the input then a default Space named <Zone Name> will be created. If some surfaces in a Zone are assigned to a Space and some are not, then a default Space named <Zone Name>-Remainder will be created. Input references to Space Names must have a matching Space object. Default space names may not be referenced in the input except for **Output:Variable** keys).

### 1.10.3.1 Inputs

#### 1.10.3.1.1 Field: Name

The name of the Zone object. This name must be unique across Zone, Space, ZoneList, and SpaceList names.

#### 1.10.3.1.2 Field: Direction of Relative North

The Zone North Axis is specified **relative to the Building North Axis**. This value is specified in degrees (clockwise is positive). For more information, see the figure below as well as the description under “[GlobalGeometryRules](#)”.

#### 1.10.3.1.3 Field(s): (X,Y,Z) Origin

The X,Y,Z coordinates of a zone origin can be specified, for convenience in vertex entry. Depending on the values in “[GlobalGeometryRules](#)” (see description later in this section), these will be used to completely specify the building coordinates in “world coordinate” or not. Zone Origin coordinates are specified **relative to the Building Origin (which always 0,0,0)**. The following figure illustrates the use of Zone North Axis as well as Zone Origin values.

#### 1.10.3.1.4 Field: Type

Zone type is currently unused.

#### 1.10.3.1.5 Field: Multiplier

Zone Multiplier is designed as a “multiplier” for floor area, zone loads, and energy consumed by internal gains. It takes the calculated load for the zone and multiplies it, sending the multiplied load to the attached HVAC system. The HVAC system size is specified to meet the entire multiplied zone load and will report the amount of the load met in the Zone Air System Sensible Heating or Cooling Energy/Rate output variable. Autosizing automatically accounts for multipliers. Metered energy consumption by internal gains objects such as Lights or Electric Equipment will be multiplied. The default is 1.

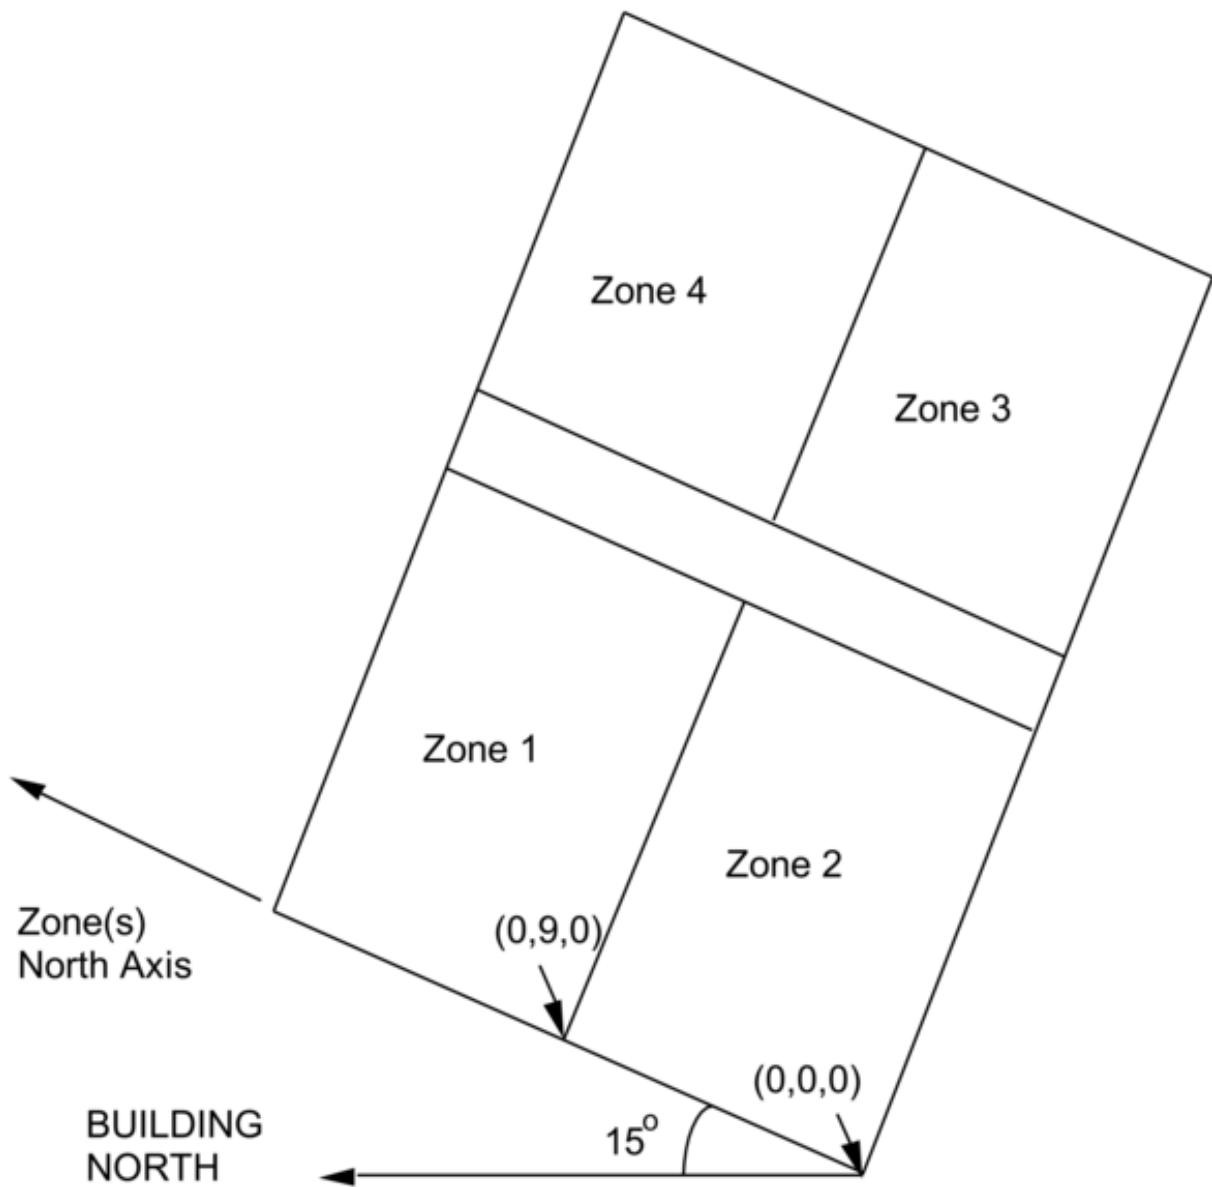

Figure 1.29: Illustration of Zone North Axis and Origins

#### 1.10.3.1.6 Field: Ceiling Height

Zone ceiling height is used in several areas within EnergyPlus (such as various room models, some convection coefficient calculations and, primarily, in calculating zone volume in the absence of other parameters). Energyplus automatically calculates the zone ceiling height (m) from the average height of the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone ceiling height will be used in subsequent calculations. If this field is positive, then the calculated zone ceiling height will not be used – the number entered here will be used as the zone ceiling height. If this number differs significantly from the calculated ceiling height, then a warning message will be issued. If a zone ceiling height is entered, but no Volume is entered, then the floor area (if there is one) times the zone ceiling height will be used as the volume.

Note that the Zone Ceiling Height is the distance from the Floor to the Ceiling in the Zone, not an absolute height from the ground.

#### 1.10.3.1.7 Field: Volume

Zone volume is used in several areas within EnergyPlus (such as calculating air change rates for reporting or flow when air change rates are chosen as input, daylighting calculations, some convection coefficient calculations). EnergyPlus automatically calculates the zone volume ( $\text{m}^3$ ) from the zone geometry given by the surfaces that belong to the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone volume will be used in subsequent calculations. If this field is positive, then it will be used as the zone volume. If this number differs significantly from the calculated zone volume a warning message will be issued. For autocalculate to work properly, the zone must be enclosed by the entered walls. Note that indicating the volume to be calculated but entering a positive ceiling height in the previous field will cause the volume to be calculated as the floor area (if  $> 0$ ) times the entered ceiling height; else the volume will be calculated from the described surfaces. If this field is positive, any ceiling height positive value will not be used in volume calculations.

#### 1.10.3.1.8 Field: Floor Area

Zone floor area is used in many places within EnergyPlus. EnergyPlus automatically calculates the zone floor area ( $\text{m}^2$ ) as the sum of the floor areas for the **Spaces** attached to this Zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone floor area will be used in subsequent calculations. If this field is positive, then it will be used as the zone floor area. If the input zone floor area does not equal the calculated floor area, the input zone floor area will take precedence, and the space floor areas will be adjusted proportionately. If the calculated floor area differs from the user input floor area by more than 5%, a warning message will be issued.

#### 1.10.3.1.9 Field: Zone Inside Convection Algorithm

The Zone Inside Convection Algorithm field is optional. This field specifies the convection model to be used for the inside face of heat transfer surfaces associated with this zone. The choices are: **Simple** (constant natural convection - ASHRAE), **TARP** (combines natural and wind-driven convection correlations from laboratory measurements on flat plates), **CeilingDiffuser** (ACH based forced and mixed convection correlations for ceiling diffuser configuration with simple natural convection limit), **AdaptiveConvectionAlgorithm** (complex arrangement of various models that adapt to various zone conditions and can be customized), **TrombeWall** (variable natural convection in an enclosed rectangular cavity), and **ASTMC1340** (mixed convection coefficients specified for attic zone). See the Inside Convection Algorithm object for further descriptions of the available models.

If omitted or blank, the algorithm specified in the **SurfaceConvectionAlgorithm:Inside** object is the default.

### 1.10.3.1.10 Field: Zone Outside Convection Algorithm

The Zone Outside Convection Algorithm field is optional. This field specifies the convection model to be used for the outside face of heat transfer surfaces associated with this zone. The choices are: **SimpleCombined**, **TARP**, **DOE-2**, **MoWiTT**, and **AdaptiveConvectionAlgorithm**. The simple convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1.143, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals.

The other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building's location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program. The TARP algorithm was developed for the TARP software and combines natural and wind-driven convection correlations from laboratory measurements on flat plates. The DOE-2 and MoWiTT were derived from field measurements. The AdaptiveConvectionAlgorithm model is an dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the [SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections](#) input object. All algorithms are described more fully in the Engineering Reference.

If omitted or blank, the algorithm specified in the [SurfaceConvectionAlgorithm:Outside](#) object is the default.

### 1.10.3.1.11 Field: Part of Total Floor Area

This optional field defaults to Yes if not specified. The field is used to show when a zone is not part of the Total Floor Area as shown in the Annual Building Utility Performance Summary tables. Specifically, when No is specified, the area is excluded from both the conditioned floor area and the total floor area in the Building Area sub table and the Normalized Metrics sub tables.

And, an IDF example:

```
Zone,
  DORM ROOMS AND COMMON AREAS,  !- Name
  0.0000000E+00,              !- Direction of Relative North {deg}
  0.0000000E+00,              !- X Origin {m}
  6.096000,                   !- Y Origin {m}
  0.0000000E+00,              !- Z Origin {m}
  1,                           !- Type
  1,                           !- Multiplier
  autocalculate,              !- Ceiling Height {m}
  autocalculate;              !- Volume {m3}
```

## 1.10.3.2 Zone Outputs

- Zone,Average,Zone Outdoor Air Drybulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wind Speed [m/s]

### 1.10.3.2.1 Zone Outdoor Air Drybulb Temperature [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

### 1.10.3.2.2 Zone Outdoor Air Wetbulb Temperature [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

#### 1.10.3.2.3 Zone Outdoor Air Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the zone centroid.

#### 1.10.4 Space Thermal Output(s)

- Zone,Sum,Space Total Internal Radiant Heating Energy [J]
- Zone,Average,Space Total Internal Radiant Heating Rate [W]
- Zone,Sum,Space Total Internal Visible Radiation Heating Energy [J]
- Zone,Average,Space Total Internal Visible Radiation Heating Rate [W]
- Zone,Sum,Space Total Internal Convective Heating Energy [J]
- Zone,Average,Space Total Internal Convective Heating Rate [W]
- Zone,Sum,Space Total Internal Latent Gain Energy [J]
- Zone,Average,Space Total Internal Latent Gain Rate [W]
- Zone,Sum,Space Total Internal Total Heating Energy [J]
- Zone,Average,Space Total Internal Total Heating Rate [W]

#### 1.10.5 Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

- Zone,Sum,Zone Total Internal Radiant Heating Energy [J]
- Zone,Average,Zone Total Internal Radiant Heating Rate [W]
- Zone,Sum,Zone Total Internal Visible Radiation Heating Energy [J]
- Zone,Average,Zone Total Internal Visible Radiation Heating Rate [W]
- Zone,Sum,Zone Total Internal Convective Heating Energy [J]
- Zone,Average,Zone Total Internal Convective Heating Rate [W]
- Zone,Sum,Zone Total Internal Latent Gain Energy [J]
- Zone,Average,Zone Total Internal Latent Gain Rate [W]
- Zone,Sum,Zone Total Internal Total Heating Energy [J]
- Zone,Average,Zone Total Internal Total Heating Rate [W]
- HVAC,Average,Zone Exfiltration Heat Transfer Rate [W]
- HVAC,Average,Zone Exfiltration Sensible Heat Transfer Rate [W]
- HVAC,Average,Zone Exfiltration Latent Heat Transfer Rate [W]
- HVAC,Average,Zone Exhaust Air Heat Transfer Rate [W]

- HVAC,Average,Zone Exhaust Air Sensible Heat Transfer Rate [W]
- HVAC,Average,Zone Exhaust Air Latent Heat Transfer Rate [W]
- HVAC,Average,Zone Air Temperature [C]
- Zone,Average,Zone Mean Air Dewpoint Temperature [C]
- Zone,Average,Zone Mean Radiant Temperature [C]
- Zone,Average,Zone Operative Temperature [C]
- HVAC,Average,Zone Air Heat Balance Internal Convective Heat Gain Rate [W]
- HVAC,Average,Zone Air Heat Balance Surface Convection Rate [W]
- HVAC,Average,Zone Air Heat Balance Interzone Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance Outdoor Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance System Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance System Convective Heat Gain Rate [W]
- HVAC,Average,Zone Air Heat Balance Air Energy Storage Rate [W]
- HVAC,Average,Zone Air Heat Balance Deviation Rate [W]
- HVAC,Sum,Zone Air System Sensible Heating Energy [J]
- HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
- HVAC,Average,Zone Air System Sensible Heating Rate [W]
- HVAC,Average,Zone Air System Sensible Cooling Rate [W]
- HVAC,Average,Zone Air Humidity Ratio[kgWater/kgDryAir]
- HVAC,Average,Zone Air Relative Humidity[%]

Two of these are of particular interest:

`Zone,Average,Zone Mean Air Temperature [C]`  
`HVAC,Average,Zone Air Temperature [C]`

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. “Zone Mean Air Temperature” is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas “Zone Air Temperature” can be reported at the HVAC timestep (which can vary).

### 1.10.5.1 Zone Mean Air Temperature [C]

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a “well stirred” model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

### 1.10.5.2 Zone Air Temperature [C]

This is very similar to the mean air temperature in the last field. The “well stirred” model for the zone is the basis, but this temperature is also available at the “detailed” system timestep.

### 1.10.5.3 Zone Mean Air Dewpoint Temperature [C]

This is the dewpoint temperature of the zone calculated from the Zone Mean Air Temperature (above), the Zone Air Humidity Ratio (below) and the outdoor barometric pressure.

### 1.10.5.4 Zone Thermostat Air Temperature [C]

This is the zone air node temperature for the well-mixed room air model, which is the default room air model type ([RoomAirModelType](#) = Mixing). But for other types of Room Air Model (the RoomAir:TemperaturePattern:<sup>\*</sup> and RoomAirSettings:<sup>\*</sup> objects) the zone thermostat air temperature may depend on the Thermostat Height and Thermostat Offset.

### 1.10.5.5 Zone Mean Radiant Temperature [C]

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is a measure of the combined effects of temperatures of surfaces within that space. Specifically it is the surface area  $\times$  emissivity weighted average of the zone inside surface temperatures (ref. Surface Inside Temperature), where emissivity is the Thermal Absorptance of the inside material layer of each surface.

### 1.10.5.6 Zone Operative Temperature [C]

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT),  $OT = 0.5*MAT + 0.5*MRT$ . This output variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

### 1.10.5.7 Zone Air Heat Balance Internal Convective Heat Gain Rate [W]

The Zone Air Heat Balance Internal Convective Heat Gain Rate is the sum, in watts, of heat transferred to the zone air from all types of internal gains, including people, lights, equipment etc. This and the following provide results on the load components of the zone air heat balance. This field is not multiplied by zone or group multipliers.

### 1.10.5.8 Zone Air Heat Balance Surface Convection Rate [W]

The Zone Air Heat Balance Surface Convection Rate is the sum, in watts, of heat transferred to the zone air from all the surfaces. This field is not multiplied by zone or group multipliers.

### 1.10.5.9 Zone Air Heat Balance Interzone Air Transfer Rate [W]

The Zone Air Heat Balance Interzone Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from other thermal zones. This field is not multiplied by zone or group multipliers.

#### 1.10.5.10 Zone Air Heat Balance Outdoor Air Transfer Rate [W]

The Zone Air Heat Balance Outdoor Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from the out side, such as infiltration. This field is not multiplied by zone or group multipliers.

#### 1.10.5.11 Zone Air Heat Balance System Air Transfer Rate [W]

The Zone Air Heat Balance System Air Transfer Rate is the sum, in watts, of heat transferred to the zone air by HVAC forced-air systems and air terminal units. Such HVAC systems are connected to the zone by an inlet node (see [ZoneHVAC:EquipmentConnections](#) input field called Zone Air Inlet Node or Node List Name) This field is not multiplied by zone or group multipliers. The Zone Air Heat Balance System Air Transfer Rate may not agree exactly with the equipment-level delivered energy transfer rate when the zone temperature is changing significantly over a timestep (e.g. during thermostat setback and setup), but the energy will balance out over time.

#### 1.10.5.12 Zone Air Heat Balance System Convective Heat Gain Rate [W]

The Zone Air Heat Balance System Convective Heat Gain Rate is the sum, in watts, of heat transferred directly to the zone air by “non-air” HVAC systems. Such HVAC systems are not connected to the zone by an inlet node but rather add or subtract heat directly to the zone air in a manner similar to internal gains. These include the convective fraction of zone HVAC baseboards and high temperature radiant systems, zone HVAC refrigeration chiller set, and the extra convective cooling provided by the cooled beam air terminal unit. This field is not multiplied by zone or group multipliers.

#### 1.10.5.13 Zone Air Heat Balance Air Energy Storage Rate [W]

The Zone Air Heat Balance Air Energy Storage Rate is the heat stored, in watts, in the zone air as result of zone air temperature changing from one timestep to the next. This field is not multiplied by zone or group multipliers.

#### 1.10.5.14 Zone Air Heat Balance Deviation Rate [W]

The Zone Air Heat Balance Deviation Rate is the imbalance, in watts, in the energy balance for zone air. The value should be near zero but will become non-zero if zone conditions are changing rapidly or erratically. This field is not multiplied by zone or group multipliers. (This output variable is only generated if the user has set a computer system environment variable `DisplayAdvancedReportVariables` equal to “yes”.)

#### 1.10.5.15 Zone Air System Sensible Heating Energy [J]

This output variable represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone Air System Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature.

This does not always indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

In addition, certain “non-air” zone-based systems will also add their heating or cooling contribution to this output variable. For example, the following zone equipment will also add their output to the appropriate heating or cooling energy/rate output variable:

- ZoneHVAC:Baseboard:RadiantConvective:Water
- ZoneHVAC:Baseboard:RadiantConvective:Steam
- ZoneHVAC:Baseboard:RadiantConvective:Electric
- ZoneHVAC:Baseboard:Convective:Water
- ZoneHVAC:Baseboard:Convective:Electric
- ZoneHVAC:CoolingPanel:RadiantConvective:Water
- ZoneHVAC:RefrigerationChillerSet

This means that system output from equipment such as high and low temperature radiant systems are NOT included in this output variable as the control of these radiant systems are handled separately with their own unique controls.

Finally, note that these variables are calculated at the system timestep. When reported at the “detailed” reporting frequency, these variables will never show heating and cooling both in the same system timestep. If reported at a frequency less than “Detailed” (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

#### 1.10.5.16 Zone Air System Sensible Cooling Energy [J]

This output variable represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers. For additional information on this output variable, see the note that accompanies the Zone Air System Sensible Heating Energy output variable above.

#### 1.10.5.17 Zone Air System Sensible Heating Rate [W]

This output variable represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers. For additional information on this output variable, see the note that accompanies the Zone Air System Sensible Heating Energy output variable above.

#### 1.10.5.18 Zone Air System Sensible Cooling Rate [W]

This output variable represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers. For additional

information on this output variable, see the note that accompanies the Zone Air System Sensible Heating Energy output variable above.

#### **1.10.5.19 Zone Air Humidity Ratio [kgWater/kgDryAir]**

This output variable represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

#### **1.10.5.20 Zone Air Relative Humidity [%]**

This output variable represents the air relative humidity after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

#### **1.10.5.21 Space or Zone Total Internal Radiant Heating Rate [W]**

#### **1.10.5.22 Space or Zone Total Internal Radiant Heating Energy [J]**

These output variables represent the sum of radiant gains from specific internal sources (e.g. equipment) throughout the space or zone in Watts (for rate) or joules. This includes radiant gain from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.10.5.23 Space or Zone Total Internal Visible Radiation Heating Rate [W]**

#### **1.10.5.24 Space or Zone Total Internal Visible Radiation Heating Energy [J]**

These output variables express the sum of heat gain in Watts (for rate) or joules that is the calculated short wavelength radiation gain from lights in the space or zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the space or zones in the simulation.

#### **1.10.5.25 Space or Zone Total Internal Convective Heating Rate [W]**

#### **1.10.5.26 Space or Zone Total Internal Convective Heating Energy [J]**

These output variables represent the sum of convective gains from specific sources (e.g. equipment) throughout the space or zone in Watts (for rate) or joules. This includes convective gain from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.10.5.27 Space or Zone Total Internal Latent Gain Rate [W]**

#### **1.10.5.28 Space or Zone Total Internal Latent Gain Energy [J]**

These output variables represent the sum of latent gains from specific internal sources (e.g. equipment) throughout the space or zone in Watts (for rate) or joules. This includes latent gain from **People**, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

**1.10.5.29 Space or Zone Total Internal Total Heating Rate [W]****1.10.5.30 Space or Zone Total Internal Total Heating Energy [J]**

These output variables represent the sum of all heat gains throughout the space or zone in Watts (for rate) or joules. This includes all heat gains from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

**1.10.5.31 Zone Exfiltration Heat Transfer Rate [W]****1.10.5.32 Zone Exfiltration Sensible Heat Transfer Rate [W]****1.10.5.33 Zone Exfiltration Latent Heat Transfer Rate [W]**

These output variables represent the heat emitted to ambient from exfiltration in Watts. The exfiltration rate is calculated by solving a mass flow balance on the zone including infiltration, ventilation, outdoor air mixing, zone-to-zone mixing, and all of the zone inlet, exhaust, and return nodes. The latent parts are determined by taking the difference between the total and the sensible rate. Positive values indicate the zone injects heat to the environment, while negative values indicate the building extracts heat from the environment.

**1.10.5.34 Zone Exhaust Air Heat Transfer Rate [W]****1.10.5.35 Zone Exhaust Air Sensible Heat Transfer Rate [W]****1.10.5.36 Zone Exhaust Air Latent Heat Transfer Rate [W]**

These output variables represent the heat emitted to ambient from exhaust air in Watts. The zone exhaust air flow rate is aggregated from the zone exhaust nodes. Positive values indicate the building injects heat to the environment, while negative values indicate the building extracts heat from the environment.

**1.10.5.37 Site Total Zone Exfiltration Heat Loss [W]**

These output variables represent the total amount of heat emitted to ambient from all zones by exfiltration in Watts. Positive values indicate the building injects heat to the environment, while negative values indicate the building extracts heat from the environment. This includes both sensible and latent heat loss from zone exfiltration.

**1.10.5.38 Site Total Zone Exhaust Air Heat Loss [W]**

These output variables represent the total amount of heat emitted to ambient from all zones by exhaust air in Watts. Positive values indicate the building injects heat to the environment, while negative values indicate the building extracts heat from the environment. This includes both sensible and latent heat loss from zone exhaust air.

## **1.10.6 ZoneList**

The ZoneList object defines a list of Zone objects. It is primarily used with the **ZoneGroup** object to provide a generalized way for doing “Floor Multipliers”. (See the **ZoneGroup** description below.) The associated ZoneList output variables also provide a way to aggregate and organize zone loads.

Zone lists are not exclusive. A zone can be referenced by more than one ZoneList object.

### 1.10.6.1 Inputs

#### 1.10.6.1.1 Field: Name

The name of the ZoneList object. This name must be unique across Zone, Space, ZoneList, and SpaceList names.

#### 1.10.6.1.2 Field: Zone <#> Name

Reference to a Zone object. This object is extensible, so additional fields of this type can be added to the end of this object.

```
ZoneList,
  Mid Floor List,  !- Name
  Mid West Zone,   !- Zone 1 Name
  Mid Center Zone, !- Zone 2 Name
  Mid East Zone;   !- Zone 3 Name
```

---

### 1.10.6.2 Outputs

The following output variables are reported by the ZoneList object:

- HVAC,Average,Zone List Sensible Heating Rate [W]
- HVAC,Average,Zone List Sensible Cooling Rate [W]
- HVAC,Sum,Zone List Sensible Heating Energy [J]
- HVAC,Sum,Zone List Sensible Cooling Energy [J]

All ZoneList variables are the sum of the corresponding Zone variables. *Zone Multiplier* fields in the Zone objects are also taken into account.

### 1.10.7 ZoneGroup

The ZoneGroup object adds a multiplier to a **ZoneList**. This can be used to reduce the amount of input necessary for simulating repetitive structures, such as the identical floors of a multi-story building. To create a “Floor Multiplier”, use the **ZoneList** object to organize several zones into a typical floor. Then use the *Zone List Multiplier* field in the ZoneGroup object to multiply the system load for the zones in the list will also be multiplied. Zones with a *Multiplier* field greater than one in the Zone object are effectively double-multiplied.

**NOTE:** Although **ZoneLists** are not exclusive by themselves, **ZoneLists** used to form a ZoneGroup are exclusive; the **ZoneLists** used with a ZoneGroup must not have any zones in common.

### 1.10.7.1 Inputs

#### 1.10.7.1.1 Tips for Multi-Story Simulations:

- For floors that are multiplied, connect exterior boundary conditions of the floor to the ceiling and vice versa.
- Since exterior convection coefficients vary with elevation, locate the typical middle floor zones mid-height between the lowest and highest middle floors to be modeled.

- Shading must be identical for all multiplied floors or less accurate results may be obtained by using the zone list multiplier.

ZoneGroup and [ZoneList](#) can also be used to simulate other repetitive cases, such as clusters of zones on the ground.

#### 1.10.7.1.2 Field: Zone Group Name

The name of the ZoneGroup object. This must be unique across ZoneGroups.

#### 1.10.7.1.3 Field: Zone List Name

Reference to a [ZoneList](#) object. The zones in the list constitute the zones in the group.

#### 1.10.7.1.4 Field: Zone List Multiplier

An integer multiplier. Zone List Multiplier is designed as a “multiplier” for floor area, zone loads, and energy consumed by internal gains. It takes the calculated load for the zone and multiplies it, sending the multiplied load to the attached HVAC system. The HVAC system size is specified to meet the entire multiplied zone load and will report the amount of the load met in the Zone Air System Sensible Heating or Cooling Energy/Rate output variable. Autosizing automatically accounts for multipliers. Metered energy consumption by internal gains objects such as Lights or Electric Equipment will be multiplied. The default is 1.

```
ZONE GROUP,
  Mid Floor,  !- Zone Group Name
  Mid Floor List,  !- Zone List Name
  8;  !- Zone List Multiplier
```

#### 1.10.7.2 Outputs

The following output variables are reported by the ZoneGroup object:

- HVAC,Average,Zone Group Sensible Heating Rate [W]
- HVAC,Average,Zone Group Sensible Cooling Rate [W]
- HVAC,Sum,Zone Group Sensible Heating Energy [J]
- HVAC,Sum,Zone Group Sensible Cooling Energy [J]

All ZoneGroup variables report the associated ZoneList value multiplied by the *Zone List Multiplier*.

### 1.10.8 Surface(s)

What's a building without surfaces?

EnergyPlus allows for several surface types:

- [BuildingSurface:Detailed](#)
- [FenestrationSurface:Detailed](#)
- [Shading:Site:Detailed](#)
- [Shading:Building:Detailed](#)

- **Shading:Zone:Detailed**

Each of the preceding surfaces has “correct” geometry specifications. BuildingSurface and Fenestration surfaces (heat transfer surfaces) are used to describe the important elements of the building (walls, roofs, floors, windows, doors) that will determine the interactions of the building surfaces with the outside environment parameters and the internal space requirements. These surfaces are also used to represent “interzone” heat transfer. All surfaces are modeled as a thin plane (with no thickness) except that material thicknesses are taken into account for heat transfer calculations.

During specification of surfaces, several “outside” environments may be chosen:

- **Ground** – when the surface is in touch with the ground (e.g. slab floors)
- **Outdoors** – when the surface is an external surface (e.g. walls, roofs, windows directly exposed to the outdoor conditions)
- **Surface** – when the surface is
  - An adiabatic internal zone surface
  - A interzone surface
- **Zone** – when the surface is
  - A interzone surface in which the other surface is not put in the input file.
- **OtherSideCoefficients** – when using a custom profile to describe the external conditions of the surface (advanced concept – covered in subject: [SurfaceProperty:OtherSideCoefficients](#))
- **OtherSideConditionsModel** – when using specially modeled components, such as active solar systems, that cover the outside surface and modify the conditions it experiences.

**Surface** items must also specify an “outside face object”. This is

- Current surface name – for adiabatic internal surfaces.
- A surface name in another zone – for interzone heat transfer.
- An “opposing” surface name (in the current zone) – for representing “middle” zones.

**Zone** items must also specify an “outside face object”. This is

- The zone that contains the other surface that is adjacent to this surface but is not entered in input.

Note that heat transfer surfaces are fully represented with each description. As stated earlier in the Construction description, materials in the construction (outside to inside) are included but film coefficients neither inside nor outside are used in the description – these are automatically calculated during the EnergyPlus run. Interzone surfaces which do not have a symmetrical construction (such as a ceiling/floor) require two Construction objects with the layers in reverse order. For example, CEILING with carpet, concrete, ceiling tile and FLOOR with ceiling tile, concrete, carpet. If interzone surfaces have a symmetrical construction, the specification for the two surfaces can reference the same Construction. When a surface is connected as the outside boundary condition for another surface, the two surfaces may be in the same plane, or they may be separated to imply thickness.

Note also that if interzone constructions include either **WindowMaterial:Glazing** or **WindowMaterial:Glazing:EquivalentLayer** then the materials properties of layers consisting of those material types will have front and back side values that may differ from one another. So, if using such materials in the definition of an interzone construction, reversed materials must also have their front and back properties inverted so as to match in reverse order. For example, if there is a single layer of glass of type **WindowMaterial:Glazing** defined for an interzone construction and the front and back properties differ, the user must define two materials with equivalent properties except that the front and back values must be reversed. This means that one material used for the definition on one side might have a front side solar reflectance at normal incidence of 0.35 and a back side solar reflectance at normal incidence of 0.25. The material used for the other side of the interzone construction must then have a front side solar reflectance at normal incidence of 0.25 and a back side solar reflectance at normal incidence of 0.35 to match properly in reverse. EnergyPlus checks for all of the user input properties for single and multiple layer interzone constructions that use these two material types to confirm that this has been done correctly so that the simulation accurately reflects the properties of the materials on each side.

**Shading** surfaces are used to describe aspects of the site which do not directly impact the physical interactions of the environmental parameters but may significantly shade the building during specific hours of the day or time so the year (e.g. trees, bushes, mountains, nearby buildings which aren't being simulated as part of this facility, etc.)

Note that surfaces which are part of the simulated building automatically shade other parts of the building as geometry and time of day dictate – there is no need on the user's part to include surfaces that might be in other zones for shading.

Another surface type:

- **InternalMass**

is used to specify the construction/material parameters and area of items within the space that are important to heat transfer calculations but not necessarily important geometrically. (For example, furniture within the space – particularly for large spaces). Internal mass can also be used for internal walls that are not needed (when FullInteriorAndExterior Solar Distribution is in effect) for solar distribution or to represent many, if not all, interior walls when solar is distributed to the floors only.

### 1.10.9 Interzone Surfaces

EnergyPlus can quite accurately simulate the surface heat exchange between two zones. However, this accuracy is not always required and using interzonal heat transfer does add to the complexity of the calculations – thus requiring more CPU time to simulate. More information about interzonal heat transfer calculations is contained in the Engineering Reference. Some simple guidelines are presented here – for three cases: adiabatic surfaces, surfaces in “middle” zones, and surfaces where heat transfer is “expected” (e.g. between a residence and an unheated, attached garage).

- Adiabatic Surfaces – These surfaces would be represented as common surfaces (between two zones) where both zones are typically the same temperature. Thus, no transfer is expected in the surface from one zone to the next. These surfaces should be described as simply internal surfaces for the zone referencing as their Outside Boundary Condition Object (see later description in individual surface objects) their own surface names.

- Surfaces in Middle Zones – Middle zones in a building can be simulated using a judicious use of surfaces and zone multipliers to effect the correct “loads” for the building. Thus, middle zone behavior can be simulated without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.
- Surfaces between Zones with differing temperatures – These zones represent the true use of interzone surfaces. In a residence that has an attached garage, the garage may be unheated/uncooled or at least not conditioned to the same degree as the residence interior. In this case, EnergyPlus can be used to accurately calculate the effects of the differently conditioned space to the other spaces.

### 1.10.10 Surface View Factors

EnergyPlus uses an area weighted approximation to calculate “view factors” between surfaces within a thermal zone. Each surface uses the total area that it can “see” among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that is visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this simple view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt (“same” being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surface is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be “around the corner” from each other and in reality not see each other at all. Rooms are assumed to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1, 3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

### 1.10.11 GlobalGeometryRules

Before the surface objects are explained in detail, a description of geometric parameters used in EnergyPlus will be given. Since the input of surface vertices is common to most of the surface types, it will also be given a separate discussion.

Some flexibility is allowed in specifying surface vertices. This flexibility is embodied in the GlobalGeometryRules class/object in the input file. Note that the parameters specified in this statement are used for all surface vertex inputs – there is no further “flexibility” allowed.

In order to perform shadowing calculations, the building surfaces must be specified. EnergyPlus uses a three dimensional (3D) Cartesian coordinate system for surface vertex specification. This Right Hand coordinate system has the X-axis pointing east, the Y-axis pointing north, and the Z-axis pointing up. See figure below.

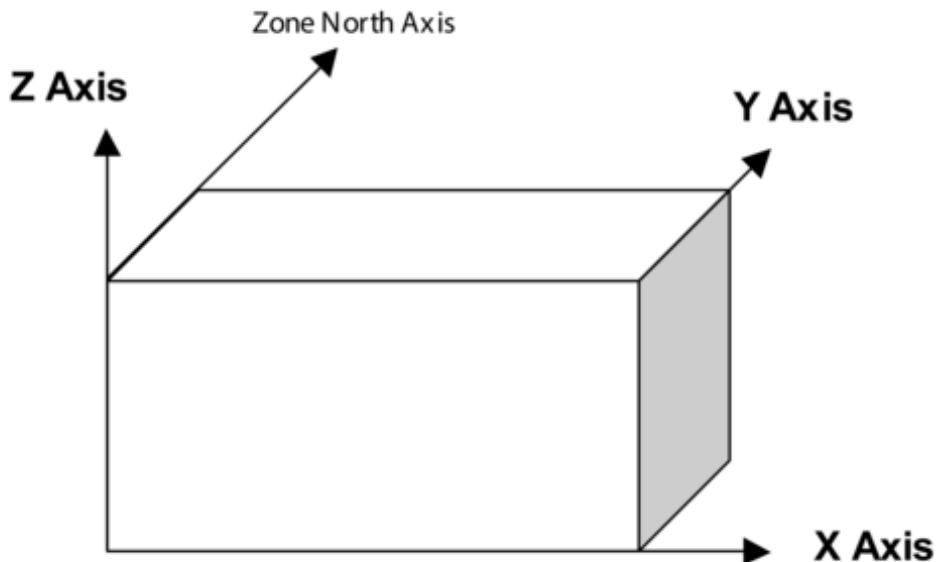

Figure 1.30: EnergyPlus Coordinate System

#### 1.10.11.1 Inputs

##### 1.10.11.1.1 Field: Starting Vertex Position

The shadowing algorithms in EnergyPlus rely on surfaces having vertices in a certain order and positional structure. Thus, the surface translator needs to know the starting point for each surface entry. The choices are: UpperLeftCorner, LowerLeftCorner , UpperRightCorner, or LowerRightCorner. Since most surfaces will be 4 sided, the convention will specify this position as though each surface were 4 sided. Extrapolate 3 sided figures to this convention. For 5 and more sided figures, again, try to extrapolate the best “corner” starting position.

##### 1.10.11.1.2 Field: Vertex Entry Direction

Surfaces are always specified as being viewed from the outside of the zone to which they belong. (Shading surfaces are specified slightly differently and are discussed under the particular types). EnergyPlus

needs to know whether the surfaces are being specified in counterclockwise or clockwise order (from the Starting Vertex Position). EnergyPlus uses this to determine the outward facing normal for the surface (which is the *facing angle* of the surface – very important in shading and shadowing calculations).

#### 1.10.11.1.3 Field: Coordinate System

Vertices can be specified in two ways: using **World** coordinates, or a **Relative** coordinate specification. Relative coordinates allow flexibility of rapid change to observe changes in building results due to orientation and position. **World** coordinates will facilitate use within a CADD system structure.

**Relative** coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the surface in 3D coordinate space. **World** coordinates do not use these values.

Typically, all zone origin values for “World” coordinates will be (0,0,0) but Building and Zone North Axis values may be used in certain instances (namely the Daylighting Coordinate Location entries).

#### 1.10.11.1.4 Field: Daylighting Reference Point Coordinate System

Daylighting reference points need to be specified as well. Again, there can be two flavors; **Relative** and **World**. Daylighting reference points must fit within the zone boundaries.

**Relative** coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the reference point in 3D coordinate space. **World** coordinates do not use these values.

#### 1.10.11.1.5 Field: Rectangular Surface Coordinate System

Simple, rectangular surfaces ([Wall:Exterior](#), [Wall:Adiabatic](#), [Wall:Underground](#), [Wall:Interzone](#), [Roof](#), [Ceiling:Adiabatic](#), [Ceiling:Interzone](#), [Floor:GroundContact](#), [Floor:Adiabatic](#), [Floor:Interzone](#)) can be specified with their Lower Left Corner as **relative** or **world**.

**Relative** (default) corners are specified relative to the Zone Origin for each surface. **World** corners would specify the absolute/world coordinate for this corner.

### 1.10.12 Surfaces

Surfaces make up the buildings and the elements that shade buildings. There are several methods to inputting surfaces, ranging from simple rectangular surfaces to detailed descriptions that describe each vertex in the order specified in the [GlobalGeometryRules](#) object. The simple, rectangular surface objects are described first with the more detailed descriptions following.

### 1.10.13 Walls

Walls are usually vertical (tilt = 90 degrees). These objects are used to describe exterior walls, interior walls (adiabatic), underground walls, and walls adjacent to other zones.

### 1.10.14 Wall:Exterior

The Wall:Exterior object is used to describe walls that are exposed to the external environment. They receive sun, wind – all the characteristics of the external world.

#### 1.10.14.1 Inputs

##### 1.10.14.1.1 Field: Name

This is a unique name associated with the exterior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.14.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.14.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.14.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.14.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.14.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

##### Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### 1.10.14.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.14.1.8 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.14.1.9 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.14.1.10 Field: Length

This field is the length of the wall in meters.

#### 1.10.14.1.11 Field: Height

This field is the height of the wall in meters.

### 1.10.15 Wall:Adiabatic

The Wall:Adiabatic object is used to describe interior walls and partitions. Adiabatic walls are used to describe walls next to zones that have the same thermal conditions (thus, no heat transfer).

### 1.10.15.1 Inputs

#### 1.10.15.1.1 Field: Name

This is a unique name associated with the interior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.15.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.15.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.15.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.15.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.15.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

##### Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### 1.10.15.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.15.1.8 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.15.1.9 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.15.1.10 Field: Length

This field is the length of the wall in meters.

#### 1.10.15.1.11 Field: Height

This field is the height of the wall in meters.

## 1.10.16 Wall:Underground

The Wall:Underground object is used to describe walls with ground contact. The temperature at the outside of the wall is the temperature in the GroundTemperature:BuildingSurface object.

### 1.10.16.1 Inputs

#### 1.10.16.1.1 Field: Name

This is a unique name associated with the underground wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.16.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones. Note that if the construction is **Construction:CfactorUndergroundWall** then the GroundFCfactoreMethod will be used for this wall.

#### 1.10.16.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.16.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See **Space** for more details.

#### 1.10.16.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.16.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

#### 1.10.16.1.7 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the **GlobalGeometryRules** object.

#### 1.10.16.1.8 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.16.1.9 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.16.1.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.10.16.1.11 Field: Length

This field is the length of the wall in meters.

### 1.10.16.1.12 Field: Height

This field is the height of the wall in meters.

## 1.10.17 Wall:Interzone

The Wall:Interzone object is used to describe walls adjacent to zones that are significantly different conditions than the zone with this wall.

### 1.10.17.1 Inputs

#### 1.10.17.1.1 Field: Name

This is a unique name associated with the interzone wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.17.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.17.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.17.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.17.1.5 Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a wall in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent wall is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### 1.10.17.1.6 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.17.1.7 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

#### 1.10.17.1.8 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

**1.10.17.1.9 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

**1.10.17.1.10 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

**1.10.17.1.11 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

**1.10.17.1.12 Field: Length**

This field is the length of the wall in meters.

**1.10.17.1.13 Field: Height**

This field is the height of the wall in meters.

## 1.10.18 Roofs/Ceilings

Roofs and ceilings are, by default, flat (tilt = 0 degrees). These objects are used to describe roofs, interior ceilings (adiabatic) and ceilings adjacent to other zones.

## 1.10.19 Roof

The Roof object is used to describe roofs that are exposed to the external environment.

**1.10.19.1 Inputs****1.10.19.1.1 Field: Name**

This is a unique name associated with the roof. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

**1.10.19.1.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

**1.10.19.1.3 Field: Zone Name**

This is the zone name to which the surface belongs. This field is required.

**1.10.19.1.4 Field: Space Name**

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See **Space** for more details.

**1.10.19.1.5 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.19.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat roofs are tilted 0 degrees and that is the default for this field.

#### 1.10.19.1.7 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### 1.10.19.1.8 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.19.1.9 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.19.1.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.19.1.11 Field: Length

This field is the length of the roof in meters.

#### 1.10.19.1.12 Field: Width

This field is the width of the roof in meters.

### 1.10.20 Ceiling:Adiabatic

The Ceiling:Adiabatic object is used to describe interior ceilings that separate zones of like conditions.

#### 1.10.20.1 Inputs

##### 1.10.20.1.1 Field: Name

This is a unique name associated with the ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

##### 1.10.20.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### 1.10.20.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

##### 1.10.20.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.20.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.20.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

#### 1.10.20.1.7 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### 1.10.20.1.8 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.20.1.9 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.20.1.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.20.1.11 Field: Length

This field is the length of the ceiling in meters.

#### 1.10.20.1.12 Field: Width

This field is the width of the ceiling in meters.

### 1.10.21 Ceiling:Interzone

The Ceiling:Interzone object is used to describe interior ceilings that separate zones of differing conditions (and expect heat transfer through the ceiling from the adjacent zone).

#### 1.10.21.1 Inputs

##### 1.10.21.1.1 Field: Name

This is a unique name associated with the interzone ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

##### 1.10.21.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### 1.10.21.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### **1.10.21.1.4 Field: Space Name**

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### **1.10.21.1.5 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a floor in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent floor is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.10.21.1.6 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### **1.10.21.1.7 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

#### **1.10.21.1.8 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### **1.10.21.1.9 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.10.21.1.10 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.10.21.1.11 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.10.21.1.12 Field: Length**

This field is the length of the ceiling in meters.

#### **1.10.21.1.13 Field: Width**

This field is the width of the ceiling in meters.

### **1.10.22 Floors**

Floors are, by default, flat (tilt = 180 degrees). These objects are used to describe floors on the ground, interior floors (adiabatic) and floors adjacent to other zones.

### **1.10.23 Floor:GroundContact**

The Floor:GroundContact object is used to describe floors that have ground contact (usually called slabs). The temperature at the outside of the floor is the temperature in the GroundTemperature:BuildingSurface object.

### 1.10.23.1 Inputs

#### 1.10.23.1.1 Field: Name

This is a unique name associated with the floor.

#### 1.10.23.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones. Note that if the construction is **Construction:FfactorGroundFloor**, then the GroundFCfactorMethod will be used with this floor.

#### 1.10.23.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.23.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See **Space** for more details.

#### 1.10.23.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.23.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

#### 1.10.23.1.7 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the **GlobalGeometryRules** object.

#### 1.10.23.1.8 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.23.1.9 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.23.1.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.23.1.11 Field: Length

This field is the length of the floor in meters.

#### 1.10.23.1.12 Field: Width

This field is the width of the floor in meters.

## 1.10.24 Floor:Adiabatic

The Floor:Adiabatic object is used to describe interior floors or floors that you wish to model with no heat transfer from the exterior to the floor.

### 1.10.24.1 Inputs

#### 1.10.24.1.1 Field: Name

This is a unique name associated with the floor.

#### 1.10.24.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.24.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.24.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.24.1.5 Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

#### 1.10.24.1.6 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

#### 1.10.24.1.7 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

#### 1.10.24.1.8 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.24.1.9 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.24.1.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.24.1.11 Field: Length

This field is the length of the floor in meters.

#### 1.10.24.1.12 Field: Width

This field is the width of the floor in meters.

### 1.10.25 Floor:Interzone

The Floor:Interzone object is used to describe floors that are adjacent to other zones that have differing conditions and you wish to model the heat transfer through the floor.

#### 1.10.25.1 Inputs

##### 1.10.25.1.1 Field: Name

This is a unique name associated with the floor.

##### 1.10.25.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### 1.10.25.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

##### 1.10.25.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

##### 1.10.25.1.5 Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a ceiling in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

##### 1.10.25.1.6 Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East = 90, South = 180, West = 270, North = 0.

##### 1.10.25.1.7 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

##### 1.10.25.1.8 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the [GlobalGeometryRules](#) object.

##### 1.10.25.1.9 Field: Starting X Coordinate

This field is the X coordinate (in meters).

### 1.10.25.1.10 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

### 1.10.25.1.11 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.10.25.1.12 Field: Length

This field is the length of the floor in meters.

### 1.10.25.1.13 Field: Width

This field is the width of the floor in meters.

## 1.10.26 Windows/Doors

The following window and door objects can be used to specify simple, rectangular doors and windows. In each case, the lower left corner (locator coordinate) of the window or door is specified **relative** to the surface it is on. Viewing the base surface as a planar surface, base the relative location from the lower left corner of the base surface. Vertex entry description as well as provisions for a few other surface types can be entered with the [FenestrationSurface:Detailed](#) object.

## 1.10.27 Window

The Window object is used to place windows on surfaces that can have windows, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects. Shades and screens may be applied by referencing this subsurface in a window shading control (ref: [WindowShadingControl](#) object). To assign a shade to a window or glass door, see [WindowMaterial:Shade](#). To assign a screen, see [WindowMaterial:Screen](#). To assign a blind, see [WindowMaterial:Blind](#). To assign switchable glazing, such as electrochromic glazing, see [WindowShadingControl](#).

### 1.10.27.1 Inputs

#### 1.10.27.1.1 Field: Name

This is a unique name associated with the window.

#### 1.10.27.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: objects: Construction, [Construction:WindowDataFile](#), [Construction:ComplexFenestrationState](#)).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref. [Construction:WindowDataFile](#) object) will be searched for that Construction Name (see “Importing Windows from WINDOW”). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### 1.10.27.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (e.g., Outside Boundary Condition = Ground) cannot contain a window. The window assumes the outward facing angle as well as the tilt angle of the base surface.

#### 1.10.27.1.4 Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: [WindowProperty:FrameAndDivider](#) object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

#### 1.10.27.1.5 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

–a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

–an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### 1.10.27.1.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### 1.10.27.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.27.1.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.27.1.9 Field: Length

This field is the length of the window in meters.

#### 1.10.27.1.10 Field: Height

This field is the height of the window in meters.

## 1.10.28 Door

The Door object is used to place opaque doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

### 1.10.28.1 Inputs

#### 1.10.28.1.1 Field: Name

This is a unique name associated with the door.

#### 1.10.28.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: Construction object)

#### 1.10.28.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. The door assumes the outward facing angle as well as the tilt angle of the base surface.

#### 1.10.28.1.4 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

- a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

- an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### 1.10.28.1.5 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### 1.10.28.1.6 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.28.1.7 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.28.1.8 Field: Length

This field is the length of the door in meters.

#### 1.10.28.1.9 Field: Height

This field is the height of the door in meters.

### 1.10.29 GlazedDoor

The GlazedDoor object is used to place doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects. Shades and screens may be applied by referencing this subsurface in a window shading control (ref: [WindowShadingControl](#) object). To assign a shade to a window or glass door, see [WindowMaterial:Shade](#). To assign a screen, see [WindowMaterial:Screen](#). To assign a blind, see [WindowMaterial:Blind](#). To assign switchable glazing, such as electrochromic glazing, see [WindowShadingControl](#).

#### 1.10.29.1 Inputs

##### 1.10.29.1.1 Field: Name

This is a unique name associated with the glass door.

##### 1.10.29.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: objects: Construction, [Construction:WindowDataFile](#), [Construction:ComplexFenestrationState](#)).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: [Construction:WindowDataFile](#) object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

##### 1.10.29.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The door assumes the outward facing angle as well as the tilt angle of the base surface.

##### 1.10.29.1.4 Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: [WindowProperty:FrameAndDivider](#) object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

### 1.10.29.1.5 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier  $> 1$  can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier  $> 1$ , you will get

- a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

- an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

### 1.10.29.1.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

### 1.10.29.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

### 1.10.29.1.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.10.29.1.9 Field: Length

This field is the length of the door in meters.

### 1.10.29.1.10 Field: Height

This field is the height of the door in meters.

## 1.10.30 Window:Interzone

The Window:Interzone object is used to place windows on surfaces that can have windows, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

### 1.10.30.1 Inputs

#### 1.10.30.1.1 Field: Name

This is a unique name associated with the window.

#### 1.10.30.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: objects: Construction, **Construction:WindowDataFile**, **Construction:ComplexFenestrationState**).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref. **Construction:WindowDataFile** object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### 1.10.30.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The window assumes the outward facing angle as well as the tilt angle of the base surface.

#### 1.10.30.1.4 Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a window in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### 1.10.30.1.5 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

–a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

–an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### 1.10.30.1.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### 1.10.30.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.30.1.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.30.1.9 Field: Length

This field is the length of the window in meters.

#### 1.10.30.1.10 Field: Height

This field is the height of the window in meters.

### 1.10.31 Door:Interzone

The Door:Interzone object is used to place opaque doors on surfaces that can have doors, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### 1.10.31.1 Inputs

##### 1.10.31.1.1 Field: Name

This is a unique name associated with the door.

##### 1.10.31.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: Construction object).

##### 1.10.31.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. The door assumes the outward facing angle as well as the tilt angle of the base surface.

##### 1.10.31.1.4 Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a door in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

##### 1.10.31.1.5 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

–a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

–an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### 1.10.31.1.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### 1.10.31.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.31.1.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.10.31.1.9 Field: Length

This field is the length of the door in meters.

#### 1.10.31.1.10 Field: Height

This field is the height of the door in meters.

### 1.10.32 GlazedDoor:Interzone

The GlazedDoor:Interzone object is used to place doors on surfaces that can have doors, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### 1.10.32.1 Inputs

##### 1.10.32.1.1 Field: Name

This is a unique name associated with the glass door.

##### 1.10.32.1.2 Field: Construction Name

This is the name of the subsurface's construction (ref: objects: Construction, Construction:WindowDataFile, Construction:ComplexFenestrationState).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: Construction:WindowDataFile object) will be searched for that Construction Name (see “Importing Windows from WINDOW”). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

### 1.10.32.1.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The door assumes the outward facing angle as well as the tilt angle of the base surface.

### 1.10.32.1.4 Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a glazed (glass) door in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

### 1.10.32.1.5 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

–a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

–an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

### 1.10.32.1.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

### 1.10.32.1.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

### 1.10.32.1.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.10.32.1.9 Field: Length

This field is the length of the door in meters.

### 1.10.32.1.10 Field: Height

This field is the height of the door in meters.

Examples of the rectangular surfaces are found in the example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2. Some examples:

### 1.10.33 Surface Vertices

Each of the following surfaces:

- **BuildingSurface:Detailed**
- **Wall:Detailed**
- **RoofCeiling:Detailed**
- **Floor:Detailed**
- **FenestrationSurface:Detailed**
- **Shading:Site:Detailed**
- **Shading:Building:Detailed**
- **Shading:Zone:Detailed**

use the same vertex input. The numeric parameters indicated below are taken from the **BuildingSurface:Detailed** definition; the others may not be exactly the same but are identical in configuration. They are also “extensible” – so, to define more vertices for these surfaces, simply add the required number of vertices (X, Y, and Z coordinates for each vertex) to the input file. Note that **FenestrationSurface:Detailed** is not extensible and is limited to 4 (max) vertices. If the Number of Surface Vertex groups is left blank or entered as **autocalculate**, EnergyPlus looks at the number of groups entered and figures out how many coordinate groups are entered.

**Note that the resolution on the surface vertex input is 1 millimeter (.001 meter). Therefore, using vertices that are very close together (< 1 mm) may result in invalid dot product and fatal errors during shading calculations.**

The figure above will help illustrate Surface Vertex entry. The convention used in “**GlobalGeometryRules**” dictates the order of the vertices (ref: **GlobalGeometryRules**). In this example, the conventions used are Starting Vertex Position = UpperLeftCorner and Vertex Entry Direction = CounterClockwise. The surfaces for this single zone are:

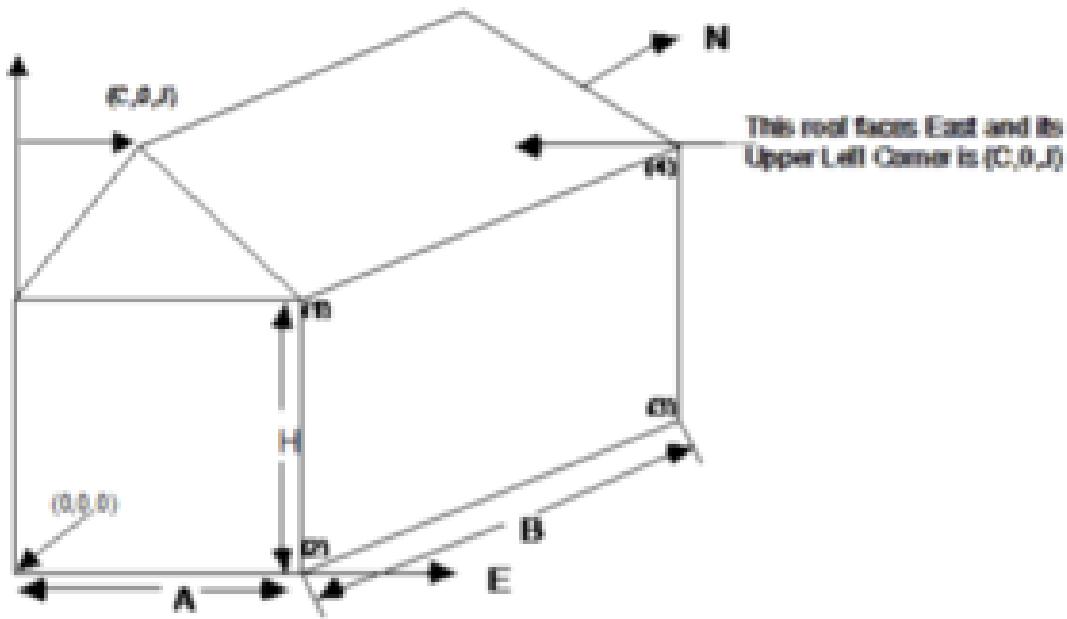

Figure 1.31: Illustration for Surface Vertices

```

4,0,0,H, 0,0,0, A,0,0, A,0,H; ! (4 vertices, South Wall)
4,A,0,H,A,0,0,A,B,0,A,B,H; ! (4 vertices, East Wall)
    ignore other walls that are not shown in this figure
4,C,0,J,A,0,H,A,B,H,C,B,J; ! (4 vertices, roof)
3,C,0,J,0,0,H,A,0,H; ! (3 vertices, gable end)
4,0,0,H, 0,0,0, A,0,0, A,0,H; ! (4 vertices, South Wall)

```

Note that in this example, point 1 of the entry is the Upper Left Corner of the rectangular surfaces and the point of the triangle for the 3 sided surface. The east wall shows the order of vertex entry. For horizontal surfaces, any vertex may be chosen as the starting position, but the Vertex Entry Direction convention must be followed. The surface details report (Output: Surfaces>List, Details;) is very useful for reviewing the accuracy of surface geometry inputs (ref: Surface Output Variables/Reports and Variable Dictionary Reports).

From the detailed vertices, EnergyPlus tries to determine the “height” and “width” of the surface. Obviously, this doesn’t work well for >4 sided surfaces; for these, if the calculated height and width are not close to the gross area for the surface, the height and width shown will be the square root of the area (and thus a square).

### 1.10.34 Building Surfaces - Detailed

A building surface is necessary for all calculations. There must be at least one building surface per zone. You can use the detailed descriptions as shown below or the simpler, rectangular surface descriptions shown earlier.

### 1.10.35 Wall:Detailed

The Wall:Detailed object is used to describe walls.

### 1.10.35.1 Inputs

#### 1.10.35.1.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.35.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.35.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.35.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.35.1.5 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

1. **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
2. **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
3. **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
4. **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
5. **Foundation** - uses an alternative model (currently only the Kiva<sup>TM</sup> model) to account for the multi-dimensional heat transfer of foundation surfaces. The Outside Boundary Condition Object will refer to the name of a [Foundation:Kiva](#) object (or be left blank to use the default foundation without extra insulation).

6. **Ground** - The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month.
7. **GroundFCfactorMethod** – if this surface is exposed to the ground and using the **Construction:CfactorUnd** then this is the choice. The temperature on the outside of this surface will be the Site:GroundTemperature:Fcfacto value for the month.
8. **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See **SurfaceProperty:OtherSideCoefficients** specification), then this is the choice. The outside boundary condition will be the name of the **SurfaceProperty:OtherSideCoefficients** specification.
9. **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See **SurfaceProperty:OtherSideConditionsModel** specification), then this the choice. The outside face environment will be the name of the **SurfaceProperty:OtherSideConditionsModel** specification.
10. **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
11. **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
12. **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
13. **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
14. **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
15. **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
16. **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.10.35.1.6 Field: Outside Boundary Condition Object

If neither Surface, Zone, Foundation, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the [SurfaceProperty:OtherSideCoefficients](#) name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the [SurfaceProperty:OtherSideConditionsModel](#) name.

#### 1.10.35.1.7 Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

#### 1.10.35.1.8 Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

#### 1.10.35.1.9 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a [DaylightingDevice:Shelf](#) or [DaylightingDevice:Tubular](#) has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1-\cos(\text{SurfTilt}))/2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If you do use the reflections option in the Solar Distribution field in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a **DaylightingDevice:Shelf** or **DaylightingDevice:Tubular**, then you still need to enter some values of View Factor to Ground. For **DaylightingDevice:Shelf** you need to enter View Factor to Ground for the window associated with the shelf. And for **DaylightingDevice:Tubular** you need to enter the View Factor to Ground for the **FenestrationSurface:Detailed** corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

#### 1.10.35.1.10 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

### 1.10.36 RoofCeiling:Detailed

The RoofCeiling:Detailed object is used to describe a roof or ceiling.

#### 1.10.36.1 Inputs

##### 1.10.36.1.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

##### 1.10.36.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### 1.10.36.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

##### 1.10.36.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See **Space** for more details.

##### 1.10.36.1.5 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

1. **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
2. **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
3. **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
4. **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
5. **Ground** – The temperature on the outside of this surface will be the Ground Temperature.
6. **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See [SurfaceProperty:OtherSideCoefficients](#) specification), then this is the choice. The outside boundary condition will be the name of the [SurfaceProperty:OtherSideCoefficients](#) specification.
7. **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See [SurfaceProperty:OtherSideConditionsModel](#) specification), then this the choice. The outside face environment will be the name of the [SurfaceProperty:OtherSideConditionsModel](#) specification.
8. **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
9. **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
10. **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
11. **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
12. **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
13. **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
14. **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.10.36.1.6 Field: Outside Boundary Condition Object

If neither Surface, Zone, Foundation, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the [SurfaceProperty:OtherSideCoefficients](#) name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the [SurfaceProperty:OtherSideConditionsModel](#) name.

#### 1.10.36.1.7 Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

#### 1.10.36.1.8 Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

#### 1.10.36.1.9 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View

Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1-\cos(\text{SurfTilt}))/2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If you **do use the reflections option in the Solar Distribution field** in your Building object input, you **do not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you **do use the reflections option AND** you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

### **1.10.36.1.10 Field: Number of Vertices**

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

## **1.10.37 Floor:Detailed**

The Floor:Detailed object is used to describe floors.

### **1.10.37.1 Inputs**

#### **1.10.37.1.1 Field: Name**

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### **1.10.37.1.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.37.1.3 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.37.1.4 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space named <Zone Name> or <Zone Name>-Remainder. See [Space](#) for more details.

#### 1.10.37.1.5 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

1. **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
2. **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
3. **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
4. **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
5. **Foundation** - uses an alternative model (currently only the Kiva<sup>TM</sup> model) to account for the multi-dimensional heat transfer of foundation surfaces. The Outside Boundary Condition Object will refer to the name of a [Foundation:Kiva](#) object (or be left blank to use the default foundation without extra insulation).
6. **Ground** - The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month..
7. **GroundFCfactorMethod** – if this surface is exposed to the ground and using the [Construction:CfactorUnderground](#) value for the month.
8. **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See [SurfaceProperty:OtherSideCoefficients](#) specification), then this is the choice. The outside boundary condition will be the name of the [SurfaceProperty:OtherSideCoefficients](#) specification.

9. **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See [SurfaceProperty:OtherSideConditionsModel](#) specification), then this the choice. The outside face environment will be the name of the [SurfaceProperty:OtherSideConditionsModel](#) specification.
10. **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
11. **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
12. **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
13. **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
14. **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
15. **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
16. **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.10.37.1.6 Field: Outside Boundary Condition Object

If neither Surface, Zone, Foundation, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the [SurfaceProperty:OtherSideCoefficients](#) name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the [SurfaceProperty:OtherSideConditionsModel](#) name.

#### 1.10.37.1.7 Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

#### 1.10.37.1.8 Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

#### 1.10.37.1.9 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If you do use the reflections option in the Solar Distribution field in your Building object input, you do not have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing

surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

#### 1.10.37.1.10 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

Some examples of using these objects:

```

#### 1.10.38 BuildingSurface:Detailed

The BuildingSurface:Detailed object can more generally describe each of the surfaces.

##### 1.10.38.1 Inputs

###### 1.10.38.1.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.10.38.1.2 Field: Surface Type

Used primarily for convenience, the surface type can be one of the choices illustrated above – Wall, Floor, Ceiling, Roof. Azimuth (facing) and Tilt are determined from the vertex coordinates. Note that “normal” floors will be tilted 180° whereas flat roofs/ceilings will be tilted 0°. EnergyPlus uses this field’s designation, along with the calculated tilt of the surface, to issue warning messages when tilts are “out of range”. Calculations in EnergyPlus use the actual calculated tilt values for the actual heat balance calculations. Note, however, that a floor tilted 0° is really facing “into” the zone and is not what you will desire for the calculations even though the coordinate may appear correct in the viewed DXF display.

“Normal” tilt for walls is 90° – here you may use the calculated Azimuth to make sure your walls are facing away from the zone’s interior.

#### 1.10.38.1.3 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.10.38.1.4 Field: Zone Name

This is the zone name to which the surface belongs. This field is required.

#### 1.10.38.1.5 Field: Space Name

This is the space name to which the surface belongs. If this field is left blank, it will be automatically assigned to a space name <Zone Name> or <Zone Name>-Remainder. See **Space** for more details.

#### 1.10.38.1.6 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

1. **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
2. **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
3. **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
4. **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See **Sun Exposure and Wind Exposure** below for further specifications on this kind of surface.

5. **Foundation** - uses an alternative model (currently only the Kiva™ model) to account for the multi-dimensional heat transfer of foundation surfaces. The Outside Boundary Condition Object will refer to the name of a **Foundation:Kiva** object (or be left blank to use the default foundation without extra insulation).
6. **Ground** - The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month.
7. **GroundFCfactorMethod** – if this surface is exposed to the ground and using the **Construction:CfactorUnd** then this is the choice. The temperature on the outside of this surface will be the Site:GroundTemperature:Fcfact value for the month.
8. **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See **SurfaceProperty:OtherSideCoefficients** specification), then this is the choice. The outside boundary condition will be the name of the **SurfaceProperty:OtherSideCoefficients** specification.
9. **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See **SurfaceProperty:OtherSideConditionsModel** specification), then this the choice. The outside face environment will be the name of the **SurfaceProperty:OtherSideConditionsModel** specification.
10. **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
11. **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
12. **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
13. **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
14. **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
15. **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
16. **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.10.38.1.7 Field: Outside Boundary Condition Object

If neither Surface, Zone, Foundation, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the [SurfaceProperty:OtherSideCoefficients](#) name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the [SurfaceProperty:OtherSideConditionsModel](#) name.

#### 1.10.38.1.8 Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

#### 1.10.38.1.9 Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

#### 1.10.38.1.10 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a [DaylightingDevice:Shelf](#) or [DaylightingDevice:Tubular](#) has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1-\cos(\text{SurfTilt}))/2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If you do use the reflections option in the Solar Distribution field in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

### 1.10.38.1.11 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

IDF example of three walls (first is an exterior wall, second and third are interzone partitions):

```

### 1.10.39 FenestrationSurface:Detailed

This surface class is used for subsurfaces, which can be of five different types: Windows, Doors, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers. A subsurface (such as a window) of a base surface (such as a wall) inherits several of the properties (such as Outside Boundary Condition, Sun Exposure, etc.) of the base surface. Windows, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers are considered to have one or more glass layers and so transmit solar radiation. Doors are considered to be opaque. For Surface Type = Window and GlassDoor, shades and screens may be applied by referencing this subsurface in a window shading control (ref: [WindowShadingControl](#) object). To assign a shade to a window or glass door, see [WindowMaterial: Shade](#). To assign a screen, see [WindowMaterial:Screen](#). To assign a blind, see [WindowMaterial:Blind](#). To assign switchable glazing, such as electrochromic glazing, see [WindowShadingControl](#).

The surface can be of 3 sides or 4 sides. A 4-sided but non-rectangular fenestration surface is allowed and will be transferred to an equivalent rectangular surface with the same area and aspect ratio for the convection calculations at window air gaps.

#### 1.10.39.1 Inputs

##### 1.10.39.1.1 Field: Name

This is a unique name associated with the heat transfer subsurface. It may be used in other places as a reference (e.g. as the opposing subsurface of an interzone window or door).

##### 1.10.39.1.2 Field: Surface Type

The choices for Surface Type are Window, Door, GlassDoor, TubularDaylightDome, and TubularDaylightDiffuser. Doors are assumed to be opaque (do not transmit solar radiation) whereas the other surface types do transmit solar radiation. Windows and Glass Doors are treated identically in the calculation of conduction heat transfer, solar gain, daylighting, etc. A Window or GlassDoor, but not a Door, can have a movable interior, exterior or between-glass shading device, such as blinds (ref: [WindowMaterial:Blind](#) object), and can have a frame and/or a divider (ref: [WindowProperty:FrameAndDivider](#) object). TubularDaylightDomes and TubularDaylightDomes are specialized subsurfaces for use with the [DaylightingDevice:Tubular](#) object to simulate Tubular Daylighting Devices (TDDs). TubularDaylightDomes and TubularDaylightDomes cannot have shades, screens or blinds. In the following, the term “window” applies to Window, GlassDoor, TubularDaylightDome, and TubularDaylightDome, if not otherwise explicitly mentioned.

As noted in the description of the [BuildingSurface:Detailed](#), Azimuth (facing angle) and Tilt are calculated from the entered vertices. Tilts of subsurfaces will normally be the same as their base surface. If these are significantly beyond the “normals” for the base surface, warning messages may be issued. If the facing angles are not correct, you may have a window pointing “into” the zone rather than out of it – this would cause problems in the calculations. Note, too, that a “reveal” (inset or outset) may occur if the plane of the subsurface is not coincident with the base surface; the reveal has an effect on shading of the subsurface.

##### 1.10.39.1.3 Field: Construction Name

This is the name of the subsurface’s construction (ref: [Construction](#) object [for Door] and [Construction](#), [Construction:ComplexFenestrationState](#), [Construction:WindowDataFile](#) objects [for Window and GlassDoor]).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: [Construction:WindowDataFile](#) object) will be searched for that Construction Name (see “Importing Windows from WINDOW”). If that file is not present or if the Construction Name does

not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### 1.10.39.1.4 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window.

#### 1.10.39.1.5 Field: Outside Boundary Condition Object

If the base surface has Outside Boundary Condition = Surface or OtherSideCoefficients, then this field must also be specified for the subsurface. Otherwise, it can be left blank.

If the base surface has Outside Boundary Condition = Zone, then this surface retains that characteristic and uses the same zone of the base surface. It can be entered here for clarity or it can be left blank.

If Outside Boundary Condition for the base surface is Surface, this field should specify the subsurface in the opposing zone that is the counterpart to this subsurface. The constructions of the subsurface and opposing subsurface must match, except that, for multi-layer constructions, the layer order of the opposing subsurface's construction must be the reverse of that of the subsurface.

If Outside Boundary Condition for the base surface is OtherSideCoefficients, this field could specify the set of [SurfaceProperty:OtherSideCoefficients](#) for this subsurface. If this is left blank, then the Other Side Coefficients of the base surface will be used for this subsurface. *Windows and GlassDoors are not allowed to have Other Side Coefficients.*

#### 1.10.39.1.6 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a Daylighting Device:Shelf or Daylighting Device:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1-\cos(\text{SurfTilt}))/2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If you do use the reflections option in the Solar Distribution field in your BUILDING object input, you do not have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a [DaylightingDevice:Shelf](#) or [DaylightingDevice:Tubular](#), then you should enter some values of View Factor to Ground. For [DaylightingDevice:Shelf](#) you need to enter View Factor to Ground for the window associated with the shelf. And for [DaylightingDevice:Tubular](#) you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device (ref: [DaylightingDevice:Tubular](#)).

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground infrared view factor.

Note 3: If the view factor to the ground is autosized and a [DaylightingDevice:Shelf](#) is present, EnergyPlus will adjust both the view factor to the ground first and then the sky so that the sum of all three view factors (to the ground, to the sky, and to the shelf) does not exceed 1.0.

#### 1.10.39.1.7 Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: [WindowProperty:FrameAndDivider](#) object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

#### 1.10.39.1.8 Field: Multiplier

Used only for Surface Type = Window, Door or Glass Door. It is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

–a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

–an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### 1.10.39.1.9 Field: Number of Vertices

The number of sides the surface has (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above. Door and GlassDoor subsurfaces are rectangular and therefore have four vertices. Window subsurfaces can be rectangular or triangular and therefore have four or three vertices, respectively.

#### 1.10.39.1.10 Fields: Vertex Coordinates

This is a total of twelve fields giving the x,y,z coordinate values of the four vertices of rectangular subsurfaces [m], or a total of nine fields giving the x,y,z coordinate values of the three vertices of triangular windows.

For triangular windows the first vertex listed can be any of the three vertices, but the order of the vertices should be counter-clockwise if VertexEntry is CounterClockWise and clockwise if VertexEntry is ClockWise (ref: [GlobalGeometryRules](#)).

An IDF example of a rectangular subsurface (Window):

```

## 1.10.40 Window Modeling Options

The following table shows what input objects/fields to use to model different window options. It also gives the name of an example input, if available, that demonstrates the option.

Table 1.14: Window Modeling Options

Option	Object/Field Variable	or	Output	Input File (distributed with install)
Build up a window from <b>layers</b>	WindowMaterial:Glazing, WindowMaterial:-Gas, WindowMaterial:Shade, WindowMaterial:Screen, WindowMaterial:Blind, Construction			WindowTests.idf
Add an <b>overhang</b>	Shading:Zone:Detailed			5ZoneAirCooled.idf
Add a <b>shading device</b>	WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind; WindowShadingControl			WindowTests.idf, PurchAir- WindowBlind.idf
<b>Control</b> a shading device	Window:ShadingControl			PurchAirWindowBlind.idf
Determine when a shading device is on in a particular timestep	Print the variable “Surface Shading Device Is On Time Fraction”			PurchAirWindowBlind.idf
Control the <b>slat angle</b> of a blind	WindowShadingControl			PurchAirWindowBlind.idf
Add a <b>frame</b>	WindowProperty:- FrameAndDivider			PurchAirWithDaylighting.idf

Table 1.14: Window Modeling Options

Option	Object/Field Variable	or	Output	Input File (distributed with install)
Add a <b>divider</b>	WindowProperty:FrameAnd- Divide			PurchAirWithDaylighting.idf
Allow window to <b>daylight</b> a zone	Daylighting:Controls			PurchAirWithDay- lighting.idf, DElight-Detailed- Comparison.idf
Find <b>solar reflected</b> onto window from neighboring buildings	Building/SolarDistribution field – uses “WithReflections”			ReflectiveAdjacent- Building.idf
Model <b>switchable glazing</b> (e.g., electrochromic glass)	WindowShadingControl			PurchAirWithDaylighting.idf
Add an <b>interior window</b>	Define two Fenestration- Surface:Detailed’s, one for each associated interior wall			PurchAirWithDoubleFacade- Daylighting.idf
<b>Track</b> how beam solar falls on interior surfaces	Building/Solar Distribution = FullInteriorAndExterior			PurchAirWithDoubleFacade- Daylighting.idf
<b>Track</b> beam solar transmitted through interior windows	Building/Solar Distribution = FullInteriorAndExterior			PurchAirWithDoubleFacade- Daylighting.idf
Add a <b>shading device on an</b> <b>interior window</b>	Not allowed			
Model an <b>airflow window</b> (aka, heat extract window)	WindowProperty:Airflow- Control			AirflowWindowsAndBetween- GlassBlinds.idf
Add a <b>storm window</b> glass layer	WindowProperty:Storm- Window			StormWindow.idf
Add <b>natural ventilation</b> through an open window	Ventilation or Airflow- Network objects (Airflow- Network:Multizone:Surface, AirflowNetwork:MultiZone:- Component:DetailedOpening, etc.)			AirflowNetwork3zvent.idf
Add <b>diffusing glass</b>	WindowMaterial:Glazing/- Solar Diffusing = Yes			
Add <b>dirt on window</b>	WindowMaterial:Glazing/- Dirt Correction Factor for Solar and Visible Transmittance			
Import window (and frame/divider if present) from <b>WINDOW</b> program	See “Importing Windows from WINDOW program”			
Find <b>daylighting through</b> <b>interior windows</b>	See “Double Facades: Daylighting through Interior Windows”			PurchAirWithDoubleFacade- Daylighting.idf

## 1.10.41 InternalMass

Any surface that would logically be described as an interior wall, floor or ceiling can just as easily be described as Internal Mass. Internal Mass surface types only exchange energy with the zone in which they are described; they do not see any other zones. There are two approaches to using internal mass. The first approach is to have several pieces of internal mass with each piece having a different construction type. The other approach is to choose an average construction type and combine all of the interior surfaces into a single internal mass. Similar to internal surfaces with an adiabatic boundary condition, the zone will only exchange energy with the inside of the Internal Mass construction. If both sides of the surface exchange energy with the zone then the user should input twice the area when defining the Internal Mass object. Note that furniture and other large objects within a zone can be described using internal mass. However, simplifying calculations using internal mass must be used with caution when the “FullInteriorAndExterior” or “FullInteriorAndExteriorWithReflections” Solar Distribution model (see Building parameters) is chosen. A single Internal Mass object can be applied to a set of zones or spaces by specifying a [ZoneList](#) or [SpaceList](#) name.

### 1.10.41.1 Inputs

#### Example

When zoning an office building, five west-facing offices have been combined into one zone. All of the offices have interior walls made of the same materials. As shown in the figure below, this zone may be described with 5 exterior walls and 11 internal walls or 1 exterior wall and 1 internal mass. Note that fewer surfaces will speed up the EnergyPlus calculations.

#### Example

A five-story building has the same ceiling/floor construction separating each of the levels. Zones that are on floors 2 through 4 may be described using a single piece of internal mass to represent both the floor and ceiling. The construction for this internal mass would be identical to the ceiling/floor construction that would be used to describe separate surfaces and the area of the internal mass surface would be the total surface area of the combined ceilings/floors (i.e. twice the total floor area).

#### 1.10.41.1.1 Field: Name

This is a unique character string associated with the internal mass surface. Though it must be unique from other surface names, it is used primarily for convenience with internal mass surfaces.

#### 1.10.41.1.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface.

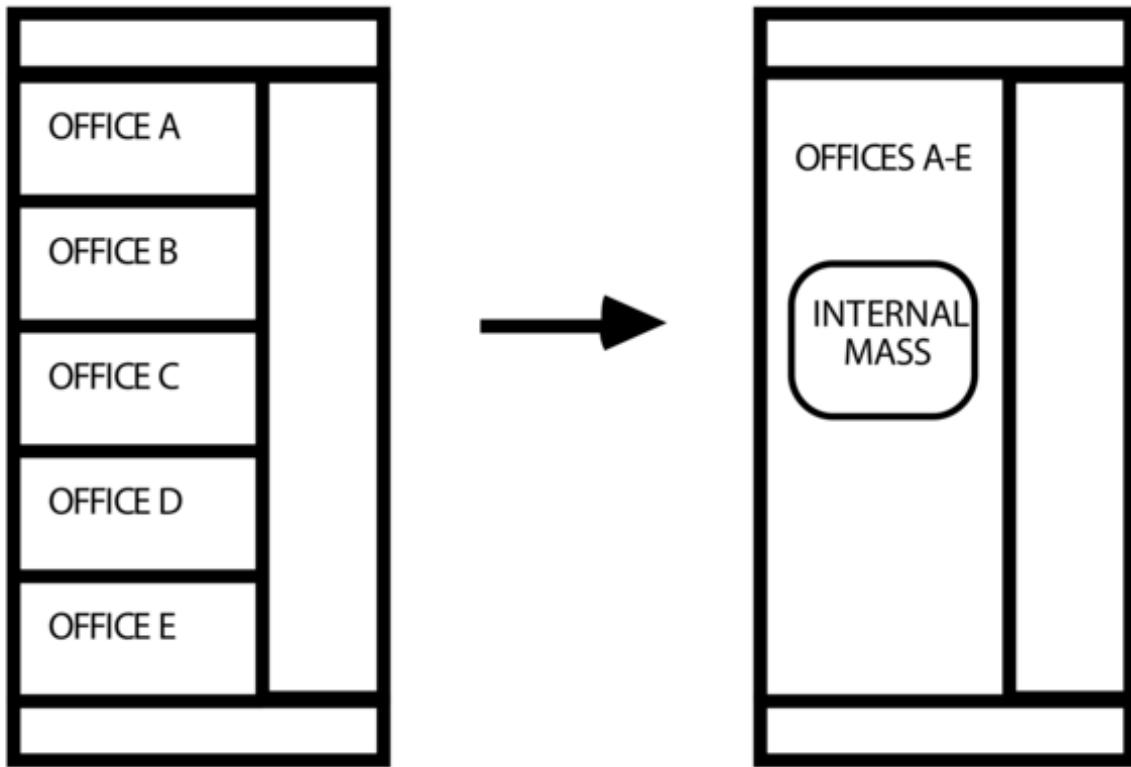

Figure 1.32: Representing 11 internal walls as internal mass

#### 1.10.41.1.3 Field: Zone or ZoneList Name

This field is the name of the **Zone** or **ZoneList** in which the internal mass will be added. When the **ZoneList** option is used then this internal mass object is applied to each of zone in the list. The name of the actual internal mass object in each zone becomes <Zone Name> <InternalMass Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.10.41.1.4 Field: Space or SpaceList Name

This field is the name of the **Space** or **SpaceList** in which the internal mass will be added. When the **SpaceList** option is used then this internal mass object is applied to each space in the list. The name of the actual internal mass object in each space becomes <Space Name> <InternalMass Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run. This field is ignored when a **ZoneList** Name is specified for **Zone** or **ZoneList** Name. If a **Space** Name is used, then the **Space** must be part of **Zone** Name. If a **SpaceList** Name is used, then the **Zone** Name is ignored (even though it is a required field), and the surface is assigned to the corresponding **Zone**(s) for each **Space** in the **SpaceList**.

#### 1.10.41.1.5 Field: Surface Area

This field is the surface area of the internal mass. The area that is specified must be the entire surface

area that is exposed to the zone. If both sides of a wall are completely within the same zone, then the area of both sides must be included when describing that internal wall.

IDF examples of Internal Mass surfaces:

## 1.10.42 Surface Output Variables/Reports

Note that Surface Outputs from specialized algorithms (such as Effective Moisture Penetration Depth (EMPD), Combined Heat and Moisture Transport (HAMT) and Conduction Finite Difference (CondFD) are discussed under the objects that describe the specialized inputs for these algorithms). You can access them via these links:

- Moisture Penetration Depth (EMPD) Outputs
- Conduction Finite Difference (CondFD) Outputs
- Heat and Moisture (HAMT) Outputs

Additionally, the output variables applicable to all heat transfer surfaces:

```
Zone,Sum,Surface Inside Face Heat Balance Calculation Iteration Count []
Zone,Average,Surface Inside Face Temperature [C]
Zone,Average,Surface Inside Face Interior Movable Insulation Temperature [C]
Zone,Average,Surface Outside Face Temperature [C]
Zone,Average,Surface Inside Face Adjacent Air Temperature [C]
Zone,Average,Surface Inside Face Convection Heat Transfer Coefficient [W/m2-K]
Zone,Average,Surface Inside Face Convection Heat Gain Rate [W]
Zone,Average,Surface Inside Face Convection Heat Gain Rate per Area [W/m2]
Zone,Sum,Surface Inside Face Convection Heat Gain Energy [J]
Zone,Average,Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate [W]
Zone,Average,Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate per Area [W/m2]
Zone,Sum,Surface Inside Face Net Surface Thermal Radiation Heat Gain Energy [J]
Zone,Average,Surface Inside Face Solar Radiation Heat Gain Rate [W]
Zone,Average,Surface Inside Face Solar Radiation Heat Gain Rate per Area [W/m2]
Zone,Sum,Surface Inside Face Solar Radiation Heat Gain Energy [J]
Zone,Average,Surface Inside Face Lights Radiation Heat Gain Rate [W]

Zone,Average, Surface Window Divider Outside Temperature [C]

```

If the user requests to display advanced report/output variables (e.g. see [Output:Diagnostics](#) keyword `DisplayAdvancedReportVariables`) the the following additional output variables are available for exterior windows and glass doors

```

Zone,Average, Surface Window Inside Face Glazing Zone Convection Heat Gain Rate [W]
Zone,Average, Surface Window Inside Face Glazing Net Infrared Heat Transfer Rate [W]
Zone,Average, Surface Window Shortwave from Zone Back Out Window Heat Transfer Rate [W]
Zone,Average, Surface Window Inside Face Frame and Divider Zone Heat Gain Rate [W]
Zone,Average, Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate [W]
Zone,Average, Surface Window Inside Face Shade Zone Convection Heat Gain Rate [W]
Zone,Average, Surface Window Inside Face Shade Net Infrared Heat Transfer Rate [W]

```

Output variables applicable to interior windows and glass doors:

```

Zone,Average, Surface Window Transmitted Solar Radiation Rate [W]
Zone,Sum, Surface Window Transmitted Solar Radiation Energy [J]
Zone,Average, Surface Window Transmitted Beam Solar Radiation Rate [W]
Zone,Sum, Surface Window Transmitted Beam Solar Radiation Energy [J]
Zone,Average, Surface Window Transmitted Beam to Beam Solar Radiation Rate [W]
Zone,Sum, Surface Window Transmitted Beam to Beam Solar Radiation Energy [J]
Zone,Average, Surface Window Transmitted Diffuse Solar Radiation Rate [W]
Zone,Sum, Surface Window Transmitted Diffuse Solar Radiation Energy [J]
Zone,Average, Surface Window Heat Gain Rate [W]
Zone,Sum, Surface Window Heat Gain Energy [J]
Zone,Average, Surface Window Heat Loss Rate [W]
Zone,Sum, Surface Window Heat Loss Energy [J]

```

If the user requests to display advanced report/output variables (e.g. see [Output:Diagnostics](#) keyword `DisplayAdvancedReportVariables`) the the following additional output variable is available for Equivalent Layer Window;

```
Zone,Average, Surface Window Inside Face Other Convection Heat Gain Rate [W]
```

Output variables applicable to interior and exterior windows and doors under certain conditions (see next three subsections for more information) are:

```

Zone,Average, Surface Window Total Absorbed Shortwave Radiation Rate Layer <x> [W]
Zone,Average, Surface Window Front Face Temperature Layer <x> [C]
Zone,Average, Surface Window Back Face Temperature Layer <x> [C]

```

### 1.10.43.1 Surface Window Total Absorbed Shortwave Radiation Rate Layer <x> [W]

This will output shortwave radiation absorbed in a window layer. The key values for this output variable are the surface name. Layers are numbered from the outside to the inside of the surface. The full listing will appear in the RDD file. Note that this variable is only defined for constructions defined by a [Construction:ComplexFenestrationState](#).

### 1.10.43.2 Surface Window Front Face Temperature Layer <x> [C]

This will output a temperature for the front face of the layer. The layer front face is considered to be the face closest to the outside environment. The full listing will appear in the RDD file. Note that this variable is only defined for constructions defined by a [Construction:ComplexFenestrationState](#). For other window constructions, this variable is also defined for the outer layer (Layer 1) only. The value will be identical to the [Surface Outside Face Temperature](#).

### 1.10.43.3 Surface Window Back Face Temperature Layer <x> [C]

This will output a temperature for the back face of the layer. The layer back face is considered to be the face closest to the inside environment. The full listing will appear in the RDD file. Note that this variable is only defined for constructions defined by a [Construction:ComplexFenestrationState](#). For other window constructions, this variable is also defined for the inner layer only. The value will be identical to the [Surface Inside Face Temperature](#).

## 1.10.44 Surface Output Variables (all heat transfer surfaces)

The various output variables related to surface heat transfer are organized around the inside and outside face of each surface. The zone heat balance model draws energy balances at each side, or face, of a surface and so each surface essentially has two sets of results. The inside face is the side of a heat transfer surface that faces toward the thermal zone. The outside face is the side of a heat transfer surface that faces away from the thermal zone, typically facing outdoors. The Key Value for these is generally the user-defined name of the surface.

### 1.10.44.1 Surface Inside Face Heat Balance Calculation Iteration Count []

This output is the number of iterations used in a part of the solution for surface heat transfer that accounts for thermal radiation heat transfer between zone surfaces. This is simply a counter on the iteration loop for inside face surface modeling. There is only one instance of this output in a given run and the Key Value is “Simulation.”

### 1.10.44.2 Surface Inside Face Temperature [C]

This is the temperature of the surface’s inside face, in degrees Celsius. Former Name: Prior to version 7.1 this output was called Surface Inside Temperature.

### 1.10.44.3 Surface Inside Face Interior Movable Insulation Temperature [C]

This is the temperature of movable insulation installed on the inside of the construction at the movable insulation’s inside face (the one facing the zone), in degrees Celsius. This variable is only valid when the surface has movable insulation and the movable insulation is actually scheduled to be present. For surfaces that have no movable insulation or the movable insulation is not scheduled to be present, the value of this variable is set to the Surface Inside Face Temperature. It should be noted that users can limit how

often this output variable is generating by using a schedule to control when this output is produced. For example, this user could add the following syntax to an input file that includes movable insulation:

```
Output:Variable,Zone1:WestWall, Surface Inside Face Interior Movable Insulation Temperature,timestep,
MovableInsulationSchedule;
```

In this example, interior movable insulation is used on the west wall of zone 1 and is only present when the schedule (MovableInsulationSchedule) is greater than zero. Adding this output variable syntax to the input file reports the temperature at the inside face of the interior movable insulation only when the movable insulation is present. The use of the movable insulation schedule in the output variable designation limits when this value shows up in the EnergyPlus output file to when it is actually scheduled to be present. At other times, no value will be reported. The limiting of when the output is generated allows the user to generate useful statistics instead of having those statistics influenced by values for when the movable insulation is not present. If the user does not use the output variable schedule feature, the output for this variable will equal the surface inside face temperature when the movable insulation is not present.

#### **1.10.44.4 Surface Outside Face Temperature [C]**

This is the temperature of the surface's outside face, in degrees Celsius. Former Name: Prior to version 7.1, this output was called Surface Outside Temperature.

#### **1.10.44.5 Surface Inside Face Adjacent Air Temperature [C]**

This is the effective bulk air temperature used for modeling the inside surface convection heat transfer. This is the same as the zone mean air temperature when using the mixing model for roomair. However, if more advanced roomair models are used, this variable will report the air temperature predicted by the roomair model as it was used in the surface heat balance model calculations. Former Name: Prior to version 7.1, this output was called Surface Int Adjacent Air Temperature.

#### **1.10.44.6 Surface Inside Face Convection Heat Gain Rate [W]**

#### **1.10.44.7 Surface Inside Face Convection Heat Gain Rate per Area [W/m<sup>2</sup>]**

#### **1.10.44.8 Surface Inside Face Convection Heat Gain Energy [J]**

These “inside face convection heat gain” output variables describe the heat transferred by convection between the inside face and the zone air. The values can be positive or negative with positive indicating heat is being added to the surface's face by convection. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called “Surface Int Convection Heat \*” and had used the opposite sign convention.

#### **1.10.44.9 Surface Inside Face Convection Heat Transfer Coefficient [W/m<sup>2</sup>-K]**

This is the coefficient that describes the convection heat transfer. It is the value of “Hc” in the classic convection model  $Q = Hc^* A^* (T - T)$ . This is the result of the surface convection algorithm used for the inside face. Former Name: Prior to version 7.1, this output was called “Surface Int Convection Coeff.”

**1.10.44.10 Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate [W]****1.10.44.11 Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.12 Surface Inside Face Net Surface Thermal Radiation Heat Gain Energy [J]**

These “inside face net surface thermal radiation heat gain” output variables describe the heat transferred by longwave infrared thermal radiation exchanges between the inside faces of other surfaces in the zone. The values can be positive or negative with positive indicating heat is being added to the surface’s face by thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

**1.10.44.13 Surface Inside Face Solar Radiation Heat Gain Rate [W]****1.10.44.14 Surface Inside Face Solar Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.15 Surface Inside Face Solar Radiation Heat Gain Energy [J]**

These “inside face solar radiation heat gain” output variables describe the heat transferred by solar radiation onto the inside face. The values are always positive and indicate heat is being added to the surface’s face by solar radiation. This is sunlight that has entered the zone through a window and been absorbed on the inside face of the surface. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

**1.10.44.16 Surface Inside Face Lights Radiation Heat Gain Rate [W]****1.10.44.17 Surface Inside Face Lights Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.18 Surface Inside Face Lights Radiation Heat Gain Energy [J]**

These “inside face lights radiation heat gain” output variables describe the heat transferred by shortwave radiation onto the inside face. The values are always positive and indicate heat is being added to the surface’s face by shortwave radiation that emanated from electric lighting equipment and was absorbed by the surface. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

**1.10.44.19 Surface Inside Face Internal Gains Radiation Heat Gain Rate [W]****1.10.44.20 Surface Inside Face Internal Gains Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.21 Surface Inside Face Internal Gains Radiation Heat Gain Energy [J]**

These “inside face internal gains radiation heat gain” output variables describe the heat transferred by longwave infrared thermal radiation onto the inside face that emanated from internal gains such as lights, electric equipment, and people. The values are always positive and indicate heat is being added to the surface’s face by the absorption of longwave thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

**1.10.44.22 Surface Inside Face System Radiation Heat Gain Rate [W]****1.10.44.23 Surface Inside Face System Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.24 Surface Inside Face System Radiation Heat Gain Energy [J]**

These “inside face system radiation heat gain” output variables describe the heat transferred by infrared thermal radiation onto the inside face that emanated from HVAC equipment such as baseboard heaters or high-temperature radiant heating panels. The values are always positive and indicate heat is being added to the surface’s face by the absorption of thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

**1.10.44.25 Surface Outside Face Convection Heat Gain Rate [W]****1.10.44.26 Surface Outside Face Convection Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.27 Surface Outside Face Convection Heat Gain Energy [J]**

These “outside face convection” output variables describe heat transferred by convection between the outside face and the surrounding air. The values can be positive or negative with positive values indicating heat is added to the surface face by convection heat transfer. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called “Surface Ext Convection Heat \*” and used the opposite sign convention.

**1.10.44.28 Surface Outside Face Convection Heat Transfer Coefficient [W/m<sup>2</sup>-K]**

This is the coefficient that describes the convection heat transfer. It is the value of “Hc” in the classic convection model  $Q = Hc^* A^* (T - T)$ . This is the result of the surface convection algorithm used for the outside face. Former Name: Prior to Version 7.1, this output was called “Surface Ext Convection Coeff.”

**1.10.44.29 Surface Outside Face Net Thermal Radiation Heat Gain Rate [W]****1.10.44.30 Surface Outside Face Net Thermal Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.44.31 Surface Outside Face Net Thermal Radiation Heat Gain Energy [J]**

These “outside face net thermal radiation” output variables describe the heat transferred by longwave infrared thermal radiation exchanges between the surface and the surroundings of the outside face. This is the net of all forms of longwave thermal infrared radiation heat transfer. The values can be positive or negative with positive indicating the net addition of heat to the outside face. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called “Surface Ext Thermal Radiation Heat \*” and used the opposite sign convention.

- 1.10.44.32 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Rate [W]**
- 1.10.44.33 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Rate per Area [W/m<sup>2</sup>]**
- 1.10.44.34 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Energy [J]**

Beam solar radiation from the exterior windows in a zone incident on the inside face of a surface in the zone. If Solar Distribution in the BUILDING object is equal to MinimalShadowing or FullExterior, it is assumed that all beam solar from exterior windows falls on the floor. In this case the value of this output variable can be greater than zero only for floor surfaces. If Solar Distribution equals FullInteriorExterior the program tracks where beam solar from exterior windows falls inside the zone, in which case the value of this variable can be greater than zero for floor as well as wall surfaces. Different versions of the report are available including the basic incident rate (W), a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

- 1.10.44.35 Surface Inside Face Interior Windows Incident Beam Solar Radiation Rate [W]**
- 1.10.44.36 Surface Inside Face Interior Windows Incident Beam Solar Radiation Rate per Area [W/m<sup>2</sup>]**
- 1.10.44.37 Surface Inside Face Interior Windows Incident Beam Solar Radiation Energy [J]**

Beam solar radiation from the interior (i.e., interzone) windows in a zone incident on the inside face of a surface in the zone. This value is calculated only if Solar Distribution in the BUILDING object is equal to FullInteriorExterior. However, the program does not track where this radiation falls. Instead, it is treated by the program as though it were diffuse radiation uniformly distributed over all of the zone surfaces. See **Figure 1.33**. Different versions of the report are available including the basic incident rate (W), a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

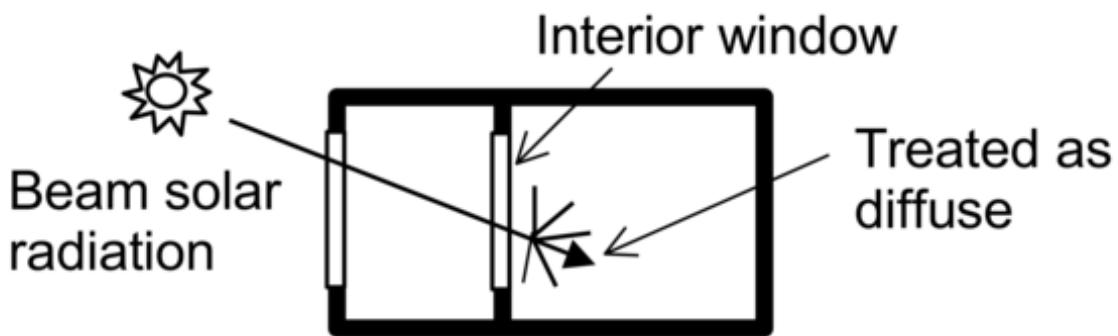

Figure 1.33: Beam solar radiation entering a zone through an interior window is distributed inside the zone as though it were diffuse radiation.

#### 1.10.44.38 Surface Inside Face Initial Transmitted Diffuse Absorbed Solar Radiation Rate [W]

As of Version 2.1, diffuse solar transmitted through exterior and interior windows is no longer uniformly distributed. Instead, it is distributed according to the approximate view factors between the transmitting window and all other heat transfer surfaces in the zone. This variable is the amount of transmitted diffuse solar that is initially absorbed on the inside of each heat transfer surface. The portion of this diffuse solar that is reflected by all surfaces in the zone is subsequently redistributed uniformly to all heat transfer surfaces in the zone, along with interior reflected beam solar and shortwave radiation from lights. The total absorbed shortwave radiation is given by the next variable.

#### 1.10.44.39 Surface Inside Face Absorbed Shortwave Radiation Rate [W]

As of Version 2.1, the previous variable plus absorbed shortwave radiation from uniformly distributed initially-reflected diffuse solar, reflected beam solar, and shortwave radiation from lights. This sum is the power of all sources of solar and visible radiation absorbed by the surface at the inside face.

#### 1.10.44.40 Surface Construction Index []

The variable reports an index that points to specific Construction. The variable is an additional output variable when [Output:Diagnostics](#), [DisplayAdvancedReportVariables](#); is given in an input file.

In order to find a corresponding construction using the index, following steps are suggested:

1. Find a surface name from Surface Construction Index in the .csv file
2. Search the surface name in lines starting with HeatTransfer Surface in the .eio file
3. The seventh item is the construction name with matched surface name.

### 1.10.45 Surface Output Variables (exterior heat transfer surfaces)

#### 1.10.45.1 Surface Outside Face Outdoor Air Drybulb Temperature [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid. Former Name: Prior to version 7.1, this output was called “Surface Ext Outdoor Dry Bulb.”

#### 1.10.45.2 Surface Outside Face Outdoor Air Wetbulb Temperature [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid. Former Name: Prior to version 7.1, this output was called “Surface Ext Outdoor Wet Bulb.”

#### 1.10.45.3 Surface Outside Face Outdoor Air Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid. This value may differ from site wind speed depending on the height of the surface (ref. [Site:HeightVariation](#)). In addition, the value may be different from the site wind speed when using [OutdoorAir:Node](#) with [SurfaceProperty:LocalEnvironment](#) or [ZoneProperty:LocalEnvironment](#). It can also be modified using EMS. Former Name: Prior to version 7.1, this output was called “Surface Ext Wind Speed.”

#### 1.10.45.4 Surface Outside Face Outdoor Air Wind Direction [deg]

This output reports the actual wind direction at the outside face of a surface. As with the wind speed variable above, this value may be different from the site wind direction when using [OutdoorAir:Node](#) with

**SurfaceProperty:LocalEnvironment** or **ZoneProperty:LocalEnvironment**. It can also be modified using EMS.

#### 1.10.45.5 Surface Outside Face Sunlit Area [m<sup>2</sup>]

The outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation.

#### 1.10.45.6 Surface Outside Face Sunlit Fraction []

The fraction of the outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation. Equals Surface Outside Face Sunlit Area divided by total surface area.

#### 1.10.45.7 Surface Outside Face Thermal Radiation to Air Heat Transfer Coefficient [W/m<sup>2</sup>-K]

This is the coefficient that describes thermal radiation heat transfer between the outside face and the air mass surrounding the surface. It is the value of “Hr” in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{surfodb})$  when applied to the ambient air. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{surfodb}$  = Surface Outside Face Outdoor Air Drybulb Temperature. Former Name: Prior to version 7.1, this output was called “Surface Ext Rad to Air Coeff.”

#### 1.10.45.8 Surface Outside Face Thermal Radiation to Sky Heat Transfer Coefficient [W/m<sup>2</sup>-K]

This is the coefficient that describes thermal radiation heat transfer between the outside face and the sky surrounding the surface. It is the value of “Hr” in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{sky})$  when applied to the sky. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{sky}$  = Site Sky Temperature. Former Name: Prior to version 7.1, this output was called “Surface Ext Rad to Sky Coeff.”

#### 1.10.45.9 Surface Outside Face Thermal Radiation to Ground Heat Transfer Coefficient [W/m<sup>2</sup>-K]

This is the coefficient that describes thermal radiation heat transfer between the outside face and the ground surrounding the surface. It is the value of “Hr” in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{odb})$  when applied to the ground. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{odb}$  = Site Outdoor Air Drybulb Temperature (used as an approximation for the ground surface temperature). Former Name: Prior to version 7.1, this output was called “Surface Ext Rad to Ground Coeff.”

#### 1.10.45.10 Surface Outside Face Thermal Radiation to Air Heat Transfer Rate [W]

This is thermal radiation heat transfer rate between the outside face and the air mass surrounding the surface.

#### 1.10.45.11 Surface Outside Face Heat Emission to Air Rate [W]

This is total heat transfer rate between the outside face and the air mass surrounding the surface by convection and thermal radiation.

**1.10.45.12 Surface Outside Face Solar Radiation Heat Gain Rate [W]****1.10.45.13 Surface Outside Face Solar Radiation Heat Gain Rate per Area [W/m<sup>2</sup>]****1.10.45.14 Surface Outside Face Solar Radiation Heat Gain Energy [J]**

These “outside face solar radiation” output variables describe the heat transferred by the absorption of solar radiation at the outside face. This is the result of incident solar radiation being absorbed at the surface face. The values are always positive.

**1.10.45.15 Surface Outside Face Incident Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The total solar radiation incident on the outside of an exterior surface. It is the sum of:

- Surface Outside Face Incident Beam Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area
- Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area
- Surface Outside Face Incident Beam To Beam Surface Reflected Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area

**1.10.45.16 Surface Outside Face Incident Beam Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar beam radiation incident on the outside of an exterior surface, including the effects of shadowing, if present. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

**1.10.45.17 Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation from the sky incident on the outside of an exterior surface, including the effects of shadowing, if present.

**1.10.45.18 Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from reflection of beam solar and sky diffuse solar from the ground. This is the sum of the next two output variables, “Surface Outside Face Incident Beam To Diffuse Ground Reflected Solar Radiation Rate per Area” and “Surface Outside Face Incident Sky Diffuse Ground Reflected Solar Radiation Rate per Area.” The reflected solar radiation from the ground is assumed to be diffuse and isotropic (there is no specular component).

If “Reflections” option is not chosen in the Solar Distribution Field in the BUILDING object, the effects of shadowing are accounted for by the user-specified value of View Factor to Ground for the surface. If “Reflections” option is chosen, the program determines the effects of shadowing, including time-varying shadowing of the ground plane by the building itself.

#### **1.10.45.19 Surface Outside Face Incident Beam To Diffuse Ground Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from the ground. It is assumed that there is no beam-to-beam (specular) component. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

#### **1.10.45.20 Surface Outside Face Incident Sky Diffuse Ground Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse solar reflection from the ground. The sky diffuse here is that directly from the sky; it excludes reflection of sky diffuse from obstructions.

#### **1.10.45.21 Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse reflection from one or more obstructions. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object.

#### **1.10.45.22 Surface Outside Face Incident Beam To Beam Surface Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar beam radiation incident on the outside of an exterior surface that arises from beam-to-beam (specular) reflection from one or more obstructions. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object. For windows, the program treats this beam radiation as diffuse radiation in calculating its transmission and absorption.

#### **1.10.45.23 Surface Outside Face Incident Beam To Diffuse Surface Reflected Solar Radiation Rate per Area [W/m<sup>2</sup>]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from building shades or building surfaces. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object.

#### **1.10.45.24 Surface Outside Face Beam Solar Incident Angle Cosine Value []**

The cosine of the angle of incidence of (unreflected) beam solar radiation on the outside of an exterior surface. The value varies from 0.0 for beam parallel to the surface (incidence angle = 90°) to 1.0 for beam perpendicular to the surface (incidence angle = 0°). Negative values indicate the sun is behind the surface, i.e the surface does not see the sun.

#### **1.10.45.25 Surface Anisotropic Sky Multiplier []**

This is the view factor multiplier for diffuse sky irradiance on exterior surfaces taking into account the anisotropic radiance of the sky. The diffuse sky irradiance on a surface is given by Anisotropic Sky Multiplier \* Diffuse Solar Irradiance.

**1.10.45.26 Surface Window BSDF Beam Direction Number []****1.10.45.27 Surface Window BSDF Beam Phi Angle [rad]****1.10.45.28 Surface Window BSDF Beam Theta Angle [rad]****1.10.46 Opaque Surface Output Variables**

The following variables apply only to opaque surfaces, where an opaque surface is considered here to be an exterior or interzone heat transfer surface of class FLOOR, WALL, ROOF or DOOR. **Note – these are advanced variables – you must read the descriptions and understand before use – then you must use the **Output:Diagnostics** object to allow reporting.**

**1.10.46.1 Surface Inside Face Conduction Heat Transfer Rate [W]****1.10.46.2 Surface Inside Face Conduction Heat Transfer Rate per Area [W/m<sup>2</sup>]****1.10.46.3 Surface Inside Face Conduction Heat Gain Rate [W]****1.10.46.4 Surface Inside Face Conduction Heat Loss Rate [W]**

These “inside face conduction” output variables describe heat flow by conduction right at the inside face of an opaque heat transfer surface. A positive value means that the conduction is from just inside the inside face toward the inside face. A negative value means that the conduction is from the inside face into the core of the heat transfer surface.

Note that Inside Face Conduction, when positive, does **not** indicate the heat flow from the surface to the zone air, which is governed by the inside face convection coefficient and the difference in temperature between the inside face and the zone air.

Different versions of the reports are available. The basic heat gain rate (W) and a per unit area flux (W/m<sup>2</sup>) can have positive or negative values with the sign convention that positive indicates heat flowing toward the face itself. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes.

**Former Name:** Prior to version 7.1, these outputs were called “Opaque Surface Inside Face Conduction \*.”

**Former Name:** For Conduction Finite Difference simulations (CondFD), CondFD Inside Surface Heat Flux is replaced with Surface Inside Face Conduction Heat Transfer Rate Per Area. Likewise for CondFD Inside Heat Flux to Surface.

**1.10.46.5 Surface Outside Face Conduction Heat Transfer Rate [W]****1.10.46.6 Surface Outside Face Conduction Heat Transfer Rate per Area [W/m<sup>2</sup>]****1.10.46.7 Surface Outside Face Conduction Heat Gain Rate [W]****1.10.46.8 Surface Outside Face Conduction Heat Loss Rate [W]**

These “outside face conduction” output variables describe heat flow by conduction right at the outside face of an opaque heat transfer surface. A positive value means that the conduction is from just inside the outside face toward the outside face. A negative value means that the conduction is from the outside face into the core of the heat transfer surface.

Note that outside face conduction, when positive, does **not** indicate the heat flow from the surface to the surrounding air, which is governed by the outside face convection coefficient and the difference in temperature between the inside face and the surrounding air.

Different versions of the reports are available. The basic heat transfer rate (W) and a per unit area flux ( $\text{W}/\text{m}^2$ ) can have positive or negative values with the sign convention that positive indicates heat flowing toward the face itself. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes.

Former Name: For Conduction Finite Difference simulations (CondFD), CondFD Outside Surface Heat Flux is replaced with Surface Outside Face Conduction Heat Transfer Rate Per Area. Likewise for CondFD Outside Heat Flux to Surface.

#### **1.10.46.9 Surface Average Face Conduction Heat Transfer Rate [W]**

#### **1.10.46.10 Surface Average Face Conduction Heat Transfer Rate per Area [ $\text{W}/\text{m}^2$ ]**

#### **1.10.46.11 Surface Average Face Conduction Heat Gain Rate [W]**

#### **1.10.46.12 Surface Average Face Conduction Heat Loss Rate [W]**

#### **1.10.46.13 Surface Average Face Conduction Heat Transfer Energy [J]**

These “average face conduction” output variables combine the inside face conduction and outside face conduction reports together to describe the conduction situation in a heat transfer surface in a nominal way. This is simply the average of the inside and outside face conduction rates, but with the sign convention for the outside face switched to match the inside face so that positive values here indicate heat flowing into the thermal zone.

Different versions of the reports are available. The basic heat conduction rate (W) and a per unit area flux ( $\text{W}/\text{m}^2$ ) can have positive or negative values with the sign convention that positive indicates heat flowing toward the thermal zone. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes (W). Finally there is a version for total energy transfer (J).

#### **1.10.46.14 Surface Heat Storage Rate [W]**

#### **1.10.46.15 Surface Heat Storage Rate per Area [ $\text{W}/\text{m}^2$ ]**

#### **1.10.46.16 Surface Heat Storage Gain Rate [W]**

#### **1.10.46.17 Surface Heat Storage Loss Rate [W]**

#### **1.10.46.18 Surface Heat Storage Energy [J]**

These “heat storage” output variables combine the inside face conduction and outside face conduction reports together to describe the thermal storage situation in a heat transfer surface in a nominal way. This is simply the difference between the inside and outside face conduction, but with the sign convention arranged so that positive values indicate heat being added to the core of the surface.

Different versions of the reports are available. The basic heat storage rate (W) and a per unit area flux ( $\text{W}/\text{m}^2$ ) can have positive or negative values with the sign convention that positive indicates heat being added to the surface’s mass. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat storage direction opposes (W). Finally there is a version for total energy stored (J).

#### **1.10.46.19 Zone Opaque Surface Inside Face Conduction [W]**

The sum of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone for both positive and negative sums. For example, assume a zone has six opaque surfaces with Opaque Surface

Inside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Inside Face Conduction =  $700 - 500 = 200$  W. Or if a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Inside Face Conduction =  $550 - 650 = -100$  W.

#### **1.10.46.20 Zone Opaque Surface Inside Faces Total Conduction Heat Gain Rate [W]**

#### **1.10.46.21 Zone Opaque Surface Inside Faces Total Conduction Heat Gain Energy [J]**

These are the power and energy sums for the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is positive. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Inside Faces Total Conduction Heat Gain Rate =  $700 - 500 = 200$  W.

#### **1.10.46.22 Zone Opaque Surface Inside Faces Total Conduction Heat Loss Rate [W]**

#### **1.10.46.23 Zone Opaque Surface Inside Faces Total Conduction Heat Loss Energy [J]**

These are the power and energy absolute value for the sums of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is negative. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Inside Faces Total Conduction Heat Loss Rate =  $|550 - 650| = |-100| = 100$  W.

#### **1.10.46.24 Zone Opaque Surface Outside Face Conduction [W]**

The sum of the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone for both positive and negative sums. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Outside Face Conduction =  $700 - 500 = 200$  W. Or if a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Outside Face Conduction =  $550 - 650 = -100$  W.

#### **1.10.46.25 Zone Opaque Surface Outside Face Conduction Gain [W]**

#### **1.10.46.26 Zone Opaque Surface Outside Face Conduction Gain Energy [J]**

These are the power and energy sums for the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone when that sum is positive. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Outside Face Conduction Gain =  $700 - 500 = 200$  W.

#### **1.10.46.27 Zone Opaque Surface Outside Face Conduction Loss [W]**

#### **1.10.46.28 Zone Opaque Surface Outside Face Conduction Loss Energy [J]**

These are the power and energy absolute value for the sums of the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone when that sum is negative. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Outside Face Conduction Loss =  $|550 - 650| = |-100| = 100$  W.

### 1.10.46.29 Surface Inside Face Beam Solar Radiation Heat Gain Rate [W]

Beam solar radiation from exterior windows absorbed on the inside face of an opaque heat transfer surface. For Solar Distribution = FullInteriorAndExterior, this quantity can be non-zero for both floor and wall surfaces. Otherwise, for Solar Distribution = FullExterior or MinimalShadowing, it can be non-zero only for floor surfaces since in this case all entering beam solar is assumed to fall on the floor. Note that this variable will not be operational (have a real value) unless there are exterior windows in the zone.

## 1.10.47 Window Output Variables

The following output variables apply to subsurfaces that are windows or glass doors. These two subsurface types are called “window” here. “Exterior window” means that the base surface of the window is an exterior wall, floor, roof or ceiling (i.e., the base surface is a [BuildingSurface:Detailed](#) with OutsideFaceEnvironment = ExteriorEnvironment). “Interior window” means that the base surface of the window is an inter-zone wall, floor or ceiling. “Glass” means a transparent solid layer, usually glass, but possibly plastic or other transparent material. “Shading device” means an interior, exterior or between-glass shade or blind, or an exterior screen (only exterior windows can have a shading device).

### 1.10.47.1 Zone Windows Total Transmitted Solar Radiation Rate [W]

### 1.10.47.2 Zone Windows Total Transmitted Solar Radiation Energy [J]

The total Surface Window Transmitted Solar Radiation Rate of all the exterior windows in a zone.

### 1.10.47.3 Zone Windows Total Heat Gain Rate [W]

### 1.10.47.4 Zone Windows Total Heat Gain Energy [J]

The sum of the heat flow from all of the exterior windows in a zone when that sum is positive. (See definition of “heat flow” under “Window Heat Gain,” below.)

### 1.10.47.5 Zone Windows Total Heat Loss Rate [W]

### 1.10.47.6 Zone Windows Total Heat Loss Energy [J]

The absolute value of the sum of the heat flow from all of the exterior windows in a zone when that sum is negative.

### 1.10.47.7 Surface Window Total Glazing Layers Absorbed Shortwave Radiation Rate [W]

### 1.10.47.8 Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

### 1.10.47.9 Surface Window Total Glazing Layers Absorbed Solar Radiation Energy [J]

The total exterior beam and diffuse solar radiation absorbed in all of the glass layers of an exterior window.

### 1.10.47.10 Surface Window Shading Device Absorbed Solar Radiation Rate [W]

Surface Window Shading Device Absorbed Solar Radiation Energy [J]

The exterior beam and diffuse solar radiation absorbed in the shading device, if present, of an exterior window.

**1.10.47.11 Surface Window Transmitted Solar Radiation Rate [W]****1.10.47.12 Surface Window Transmitted Solar Radiation Energy [J]**

The amount of beam and diffuse solar radiation entering a zone through an exterior window. It is the sum of the following two variables, “Surface Window Transmitted Beam Solar Radiation Rate” and “Surface Window Transmitted Diffuse Solar Radiation Rate.”

**1.10.47.13 Surface Window Transmitted Beam Solar Radiation Rate [W]****1.10.47.14 Surface Window Transmitted Beam Solar Radiation Energy [J]**

The solar radiation transmitted by an exterior window whose source is beam solar incident on the outside of the window. For a bare window, this transmitted radiation consists of beam radiation passing through the glass (assumed transparent) and diffuse radiation from beam reflected from the outside window reveal, if present. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of beam radiation that passes between the slats and diffuse radiation from beam-to-diffuse reflection from the slats. For a window with a screen, this value consists of direct beam radiation that is transmitted through the screen (gaps between the screen material) and diffuse radiation from beam-to-diffuse reflection from the screen material.

For each zone time step,

$$\text{Surface Window Transmitted Beam Solar Radiation Rate} = \text{Surface Window Transmitted Beam To Beam Solar Radiation Rate} + \text{Surface Window Transmitted Beam To Diffuse Solar Radiation Rate}$$

$$\text{Surface Window Transmitted Beam Solar Radiation Energy} = \text{Surface Window Transmitted Beam To Beam Solar Radiation Energy} + \text{Surface Window Transmitted Beam To Diffuse Solar Radiation Energy}$$

**1.10.47.15 Surface Window Transmitted Beam To Beam Solar Radiation Rate [W]****1.10.47.16 Surface Window Transmitted Beam To Beam Solar Radiation Energy [J]**

For a window with a blind, this transmitted radiation consists of beam radiation that passes between the slats. For a window with a screen, this value consists of direct beam radiation that is transmitted through the screen (gaps between the screen material).

**1.10.47.17 Surface Window Transmitted Beam To Diffuse Solar Radiation Rate [W]****1.10.47.18 Surface Window Transmitted Beam To Diffuse Solar Radiation Energy [J]**

For a window with a blind, this transmitted radiation consists of diffuse radiation reflected from beam by the slats. For a window with a screen, this value consists of diffuse radiation reflected by the screen material.

**1.10.47.19 Zone Exterior Windows Total Transmitted Beam Solar Radiation Rate [W]****1.10.47.20 Zone Exterior Windows Total Transmitted Beam Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Beam Solar Radiation Rate (see definition above) from all exterior windows in a zone.

**1.10.47.21 Zone Interior Windows Total Transmitted Beam Solar Radiation Rate [W]****1.10.47.22 Zone Interior Windows Total Transmitted Beam Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Beam Solar Radiation Rate (see definition above) from all interior windows in a zone.

**1.10.47.23 Surface Window Transmitted Diffuse Solar Radiation Rate [W]****1.10.47.24 Surface Window Transmitted Diffuse Solar Radiation Energy [J]**

The solar radiation transmitted by an exterior window whose source is diffuse solar incident on the outside of the window. For a bare window, this transmitted radiation consists of diffuse radiation passing through the glass. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of diffuse radiation that passes between the slats and diffuse radiation from diffuse-to-diffuse reflection from the slats. For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

**1.10.47.25 Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Rate [W]****1.10.47.26 Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Energy [J]**

The combined beam and diffuse solar that first entered adjacent zones through exterior windows in the adjacent zones, was subsequently reflected from interior surfaces in those zones (becoming diffuse through that reflection), and was then transmitted through interior windows into the current zone.

**1.10.47.27 Zone Interior Windows Total Transmitted Diffuse Solar Radiation Rate [W]****1.10.47.28 Zone Interior Windows Total Transmitted Diffuse Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Diffuse Solar Radiation Rate (see definition above) from all interior windows in a zone.

**1.10.47.29 Surface Window System Solar Transmittance []**

Effective solar transmittance of an exterior window, including effect of shading device, if present. Equal to “Surface Window Transmitted Solar Radiation Rate” divided by total exterior beam plus diffuse solar radiation incident on the window (excluding frame, if present).

**1.10.47.30 Surface Window System Solar Absorptance []**

Effective solar absorptance of an exterior window, including effect of shading device, if present. Equal to “Window Solar Absorbed: All Glass Layers” plus “Window Solar Absorbed: Shading Device” divided by total exterior beam plus diffuse solar radiation incident on window (excluding frame, if present)

### 1.10.47.31 Surface Window System Solar Reflectance []

Effective solar reflectance of an exterior window, including effect of shading device, if present. Equal to: [1.0 – “Surface Window System Solar Transmittance” – “Surface Window System Solar Absorptance”].

### 1.10.47.32 Surface Window Gap Convective Heat Transfer Rate [W]

### 1.10.47.33 Surface Window Gap Convective Heat Transfer Energy [J]

For an airflow window, the forced convective heat flow from the gap through which airflow occurs. This is the heat gained (or lost) by the air from the glass surfaces (and between-glass shading device surfaces, if present) that the air comes in contact with as it flows through the gap. If the gap airflow goes to the zone indoor air, the gap convective heat flow is added to the zone load. Applicable to exterior windows only.

### 1.10.47.34 Surface Window Heat Gain Rate [W]

### 1.10.47.35 Surface Window Heat Gain Energy [J]

The total heat flow *to the zone* from the glazing, frame and divider of an exterior window when the total heat flow is positive.

For a window *without an interior shading device*, this heat flow is equal to:

- [Surface Window Transmitted Solar Radiation Rate (see definition, above)]
- [Convective heat flow to the zone from the zone side of the glazing]
- [Net IR heat flow to the zone from zone side of the glazing]
- [Short-wave radiation from zone transmitted back out the window]
- [Convection to zone from window frame and divider, if present]

Here, short-wave radiation is that from lights and diffuse interior solar radiation.

For a window *with an interior shading device*, this heat flow is equal to:

- [Surface Window Transmitted Solar Radiation Rate]
- [Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]
- [Convective heat flow to the zone from the zone side of the shading device]
- [Net IR heat flow to the zone from the zone side of the glazing]
- [Net IR heat flow to the zone from the zone side of the shading device]
- [Short-wave radiation from zone transmitted back out the window]
- [Convection to zone from window frame and divider, if present]

The total window heat flow can also be thought of as the sum of the solar and conductive gain *to the zone* from the window.

**1.10.47.36 Surface Window Heat Loss Rate [W]****1.10.47.37 Surface Window Heat Loss Energy [J]**

The absolute value of the total heat flow through an exterior window when the total heat flow is negative. (See definition of “total heat flow” under “Surface Window Heat Gain Rate,” above.)

**1.10.47.38 Surface Window Net Heat Transfer Rate [W]****1.10.47.39 Surface Window Net Heat Transfer Energy [J]**

The total heat flow through the glazing, frame and divider of an exterior window. Negative values imply heat flow to the exterior.

The important distinction between this output variable and those for “Surface Window Heat Gain/Loss” is that this represents the net heat flow through the window and not the heat flow *to the zone*. The only difference is the heat flow *to the zone* does not account for radiation from the opaque frame and divider components. This is because these components, as a simplification, do not participate in the overall radiative exchange with other surfaces in the zone.

For a window *without an interior shading device*, this heat flow is equal to:

- [Surface Window Transmitted Solar Radiation Rate (see definition, above)]
- [Convective heat flow from the zone side of the glazing]
- [Net IR heat flow from the zone side of the glazing]
- [Short-wave radiation from zone transmitted back out the window]
- [Conduction through window frame and divider, if present]

Here, short-wave radiation is that from lights and diffuse interior solar radiation.

For a window *with an interior shading device*, this heat flow is equal to:

- [Surface Window Transmitted Solar Radiation Rate]
- [Convective heat flow from the air flowing through the gap between glazing and shading device]
- [Convective heat flow from the zone side of the shading device]
- [Net IR heat flow from the zone side of the glazing]
- [Net IR heat flow from the zone side of the shading device]
- [Short-wave radiation from zone transmitted back out the window]
- [Conduction through the window frame and divider, if present]

**1.10.47.40 Surface Window Glazing Beam to Beam Solar Transmittance []**

The fraction of exterior beam solar radiation incident on the glass of an exterior window that is transmitted through the glazing as beam radiation. This is for the base window without shading. Takes into account the angle of incidence of beam solar radiation on the glass.

#### **1.10.47.41 Surface Window Glazing Beam to Diffuse Solar Transmittance []**

The fraction of exterior beam solar radiation incident on the glazing of an exterior window that is transmitted through the glazing as diffuse radiation.

#### **1.10.47.42 Surface Window Glazing Diffuse to Diffuse Solar Transmittance []**

The fraction of exterior diffuse solar radiation incident on the glass of an exterior window that is transmitted through the glass assuming that the window has no shading device. It is assumed that incident diffuse solar is transmitted only as diffuse with no beam component.

#### **1.10.47.43 Surface Window Model Solver Iteration Count []**

The number of iterations needed by the window-layer heat balance solution to converge.

#### **1.10.47.44 Surface Window Solar Horizontal Profile Angle [deg]**

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to horizontal window elements such as horizontal reveal surfaces, horizontal frame and divider elements and horizontal slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun's ray on the vertical plane containing the outward normal. See [Figure 1.34](#).

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun's ray on the plane that contains the outward normal and is perpendicular to the ground.

If the sun is behind the window, the horizontal profile angle is not defined and is reported as 0.0.

Note that in most texts and in window equivalent layer model what we call “horizontal profile angle” is called “vertical profile angle.”

#### **1.10.47.45 Surface Window Solar Vertical Profile Angle [deg]**

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to vertical window elements such as vertical reveal surfaces, vertical frame and divider elements and vertical slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun's ray on the horizontal plane containing the outward normal. See [Figure 1.34](#).

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun's ray on the plane that contains the outward normal and is perpendicular to the plane defined above for Surface Window Solar Horizontal Profile Angle for a window of arbitrary tilt.

If the sun is behind the window, the vertical profile angle is not defined and is reported as 0.0.

Note that in most texts and in window equivalent layer model what we call “vertical profile angle” is called “horizontal profile angle.”

#### **1.10.47.46 Surface Window Outside Reveal Reflected Beam Solar Radiation Rate [W]**

#### **1.10.47.47 Surface Window Outside Reveal Reflected Beam Solar Radiation Energy [J]**

Beam solar radiation reflected from the outside reveal surfaces of a window (ref: Reveal Surfaces under [WindowProperty:FrameAndDivider](#) object). There are both rate and energy versions.

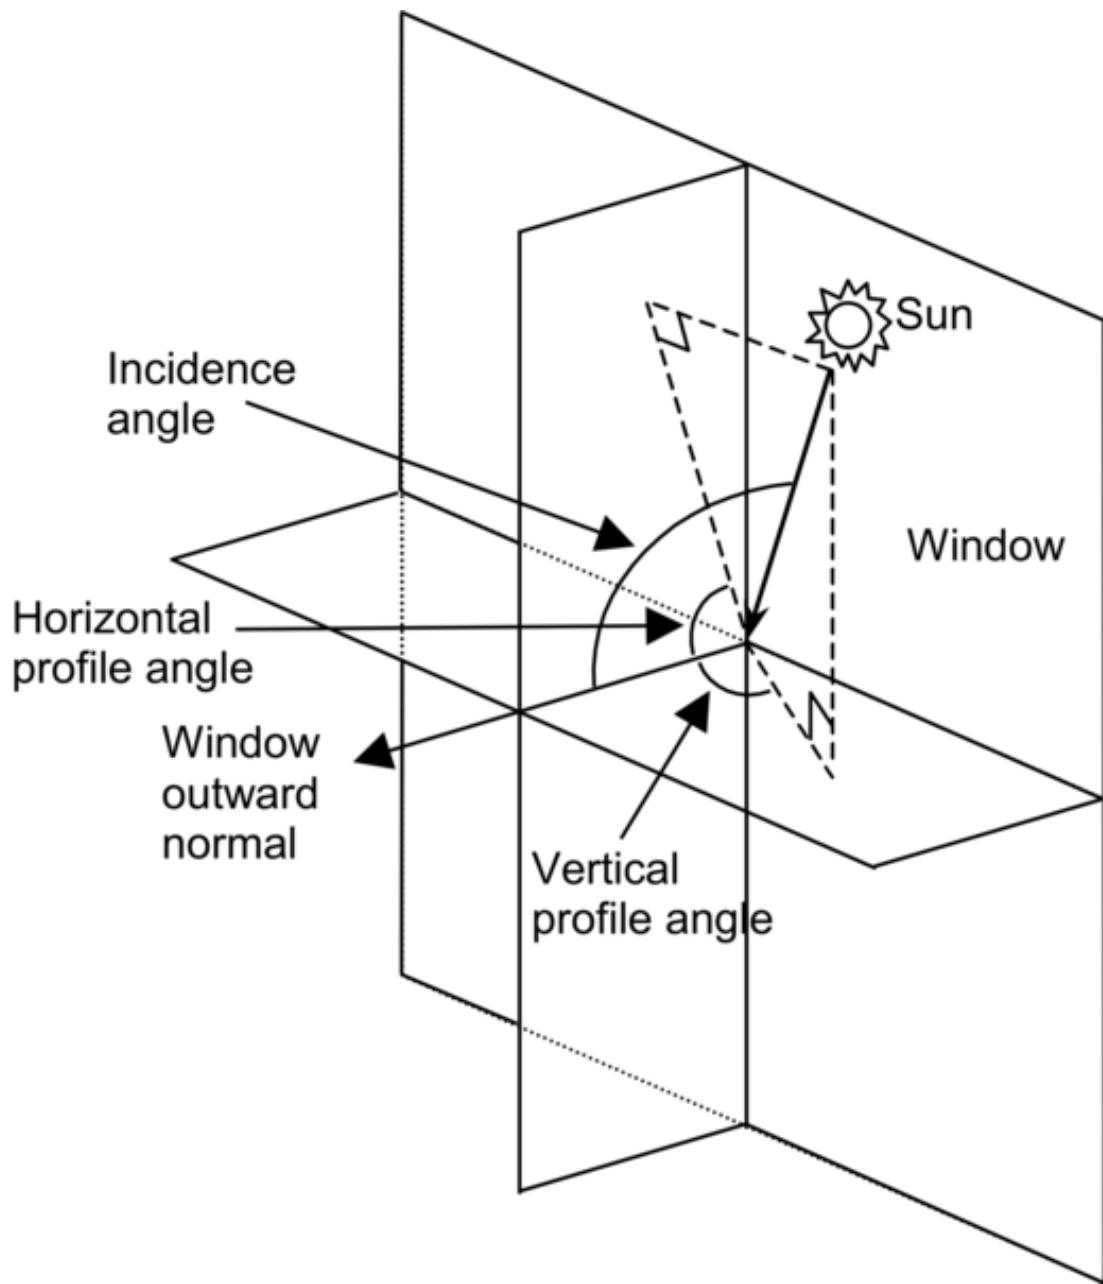

Figure 1.34: Vertical exterior window showing solar horizontal profile angle, solar vertical profile angle and solar incidence angle.

**1.10.47.48 Surface Window Inside Reveal Reflected Beam Solar Radiation Rate [W]****1.10.47.49 Surface Window Inside Reveal Reflected Beam Solar Radiation Energy [J]**

Beam solar radiation reflected from the inside reveal surfaces of a window (ref: Reveal Surfaces under **WindowProperty:FrameAndDividers** object). There are both rate and energy versions.

**1.10.47.50 Surface Window Inside Reveal Absorbed Beam Solar Radiation Rate [W]**

Beam solar radiation absorbed at the inside reveal surfaces of a window, in Watts.

**1.10.47.51 Surface Window Inside Reveal Reflected Diffuse Zone Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces of a window into the zone, in Watts.

**1.10.47.52 Surface Window Inside Reveal Reflected Diffuse Frame Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces onto the frame surfaces of a window, in Watts.

**1.10.47.53 Surface Window Inside Reveal Reflected Diffuse Glazing Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces onto the glazing surfaces of a window, in Watts.

**1.10.47.54 Surface Window Inside Face Glazing Condensation Status []**

A value of 1 means that moisture condensation will occur on the innermost glass face of an exterior window (i.e., on the glass face in contact with the zone air). Otherwise the value is 0. The condition for condensation is glass inside face temperature < zone air dewpoint temperature.

For airflow exterior windows, in which forced air passes between adjacent glass faces in double- and triple-pane windows, a value of 1 means that condensation will occur on one or both of the glass faces in contact with the airflow. In this case the condition for condensation is:

- For *airflow source = indoorair*, temperature of either face in contact with airflow < zone air dewpoint temperature.
- For *airflow source = outdoorair*, temperature of either face in contact with airflow < outside air dewpoint temperature.

As for regular windows, the value will also be 1 if condensation occurs on the innermost glass face.

**1.10.47.55 Surface Window Inside Face Frame Condensation Status []**

If an exterior window has a frame and the value of this flag is 1, condensation will occur on the inside surface of the frame. The condition for condensation is frame inside surface temperature < zone air dewpoint temperature.

### 1.10.47.56 Surface Window Inside Face Divider Condensation Status []

If an exterior window has a divider and the value of this flag is 1, condensation will occur on the inside surface of the divider. The condition for condensation is divider inside surface temperature < zone air dewpoint temperature.

### 1.10.47.57 Surface Shading Device Is On Time Fraction []

The fraction of time that a shading device is on an exterior window. For a particular simulation timestep, the value is 0.0 if the shading device is off (or there is no shading device) and the value is 1.0 if the shading device is on. (It is assumed that the shading device, if present, is either on or off for the entire timestep.) If the shading device is switchable glazing, a value of 0.0 means that the glazing is in the unswitched (light colored) state, and a value of 1.0 means that the glazing is in the switched (dark colored) state.

For a time interval longer a timestep, this is the fraction of the time interval that the shading device is on. For example, take the case where the time interval is one hour and the timestep is 10 minutes. Then if the shading device is on for two timesteps in the hour and off for the other four timesteps, then the fraction of time that the shading device is on =  $2/6 = 0.3333$ .

### 1.10.47.58 Surface Window Blind Slat Angle [deg]

For an exterior window with a blind, this is the angle in degrees between the glazing outward normal and the blind slat angle outward normal, where the outward normal points away from the front face of the slat. The slat angle varies from 0 to 180 deg. If the slat angle is 0 deg or 180 deg, the slats are parallel to the glazing and the slats are said to be “closed”. If the slat angle is 90 deg, the slats are perpendicular to the glazing and the slats are said to be “fully open”. See illustrations under [WindowMaterial:Blind](#). For blinds with a fixed slat angle, the value reported here will be constant.

For [WindowMaterial:Blind:EquivalentLayer](#) blinds the slat angle varies from -90 to 90 deg. If the slat angle is -90 deg or 90 deg, the slats are parallel to the glazing and the slats are said to be “closed”. If the slat angle is 0 deg, the slats are perpendicular to the glazing and the slats are said to be “fully open”. For blinds with a fixed slat angle, the value reported here will be constant.

### 1.10.47.59 Surface Window Blind Beam to Beam Solar Transmittance []

For an exterior window with a blind, this is the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as beam solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, and thickness, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats). The transmittance value reported here will be non-zero only when some beam solar can pass through the blind without hitting the slats.

### 1.10.47.60 Surface Window Blind Beam to Diffuse Solar Transmittance []

For an exterior window with a blind, the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

#### 1.10.47.61 Surface Window Blind Diffuse to Diffuse Solar Transmittance []

For an exterior window with a blind, the fraction of exterior diffuse solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

#### 1.10.47.62 Surface Window Blind and Glazing System Beam Solar Transmittance []

The fraction of exterior beam solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as beam solar radiation. Depends on various factors, including type of glass; solar incidence angle; slat angle, width, separation, and thickness; and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

#### 1.10.47.63 Surface Window Blind and Glazing System Diffuse Solar Transmittance []

The fraction of exterior diffuse solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as diffuse solar radiation. Depends on various factors, including type of glass and slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

#### 1.10.47.64 Surface Window Screen Beam to Beam Solar Transmittance []

For an exterior window with a screen, this is the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as beam solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

#### 1.10.47.65 Surface Window Screen Beam to Diffuse Solar Transmittance[]

For an exterior window with a screen, the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value is the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Diffuse); otherwise, this value will be zero.

#### 1.10.47.66 Surface Window Screen Diffuse to Diffuse Solar Transmittance[]

For an exterior window with a screen, the fraction of exterior diffuse solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors including screen material geometry and reflectance. This value is calculated as an average, constant For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material. For a window with a screen, this value consists

of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

#### **1.10.47.67 Surface Window Screen and Glazing System Beam Solar Transmittance[]**

The fraction of exterior beam solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as beam solar radiation. Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

#### **1.10.47.68 Surface Window Screen and Glazing System Diffuse Solar Transmittance []**

The fraction of exterior diffuse solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as diffuse solar radiation. Depends on various factors including screen material geometry and reflectance.

#### **1.10.47.69 Surface Window Transmitted Beam Solar Radiation Rate [W]**

#### **1.10.47.70 Surface Window Transmitted Beam Solar Radiation Energy [J]**

The beam solar radiation transmitted through an interior window. Calculated only if Solar Distribution = FullInteriorAndExterior in your Building input. The origin of this radiation is beam solar that enters through an exterior window in a zone and then passes through an interior window into the adjacent zone. The amount of this radiation depends on several factors, including sun position, intensity of beam solar incident on the exterior window (including effects of shadowing, if present), relative position of the exterior and interior window, and the size and transmittance of the windows. Note that if there are two or more exterior windows in a zone, then beam solar from one or more of them may pass through the same interior window. Likewise, if there are more than two or more interior windows in a zone then beam solar from a single exterior window may pass through one or more of the interior windows. There are both rate and energy versions of the output.

#### **1.10.47.71 Surface Storm Window On Off Status []**

Indicates whether a storm window glass layer is present (ref: StormWindow object). The value is **0** if the storm window glass layer is off, **1** if it is on, and **-1** if the window does not have an associated storm window. Applicable only to exterior windows and glass doors.

#### **1.10.47.72 Surface Inside Face Initial Transmitted Diffuse Transmitted Out Window Solar Radiation Rate [W]**

As of Version 2.1, the diffuse solar transmitted through exterior windows that is initially distributed to another window in the zone and transmitted out of the zone through that window. For exterior windows, this transmitted diffuse solar is “lost” to the exterior environment. For interior windows, this transmitted diffuse solar is distributed to heat transfer surfaces in the adjacent zone, and is part of the Surface Inside Face Initial Transmitted Diffuse Absorbed Solar Radiation Rate for these adjacent zone surfaces.

#### **1.10.47.73 Additional Window Outputs (Advanced)**

The following output variables for windows or glass doors are available when the user requests to display advanced output variables. These seven reports show the individual components that are combined to determine overall Surface Window Heat Gain Rate and/or Surface Window Heat Loss Rate (described above).

#### **1.10.47.74 Surface Window Inside Face Glazing Zone Convection Heat Gain Rate [W]**

The surface convection heat transfer from the glazing to the zone in watts. This output variable is the term called “[Convective heat flow to the zone from the zone side of the glazing]” under the description above for Surface Window Heat Gain Rate output variable. If the window has an interior shade or blind, then this is zero and the glazing’s convection is included in the report called “Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate”.

#### **1.10.47.75 Surface Window Inside Face Glazing Net Infrared Heat Transfer Rate [W]**

The net exchange of infrared radiation heat transfer from the glazing to the zone in watts. This output variable is the term called “[Net IR heat flow to the zone from zone side of the glazing]” under the description above for Surface Window Heat Gain Rate output variable.

#### **1.10.47.76 Surface Window Shortwave from Zone Back Out Window Heat Transfer Rate [W]**

This is the short-wave radiation heat transfer from the zone back out the window in watts. This is a measure of the diffuse short-wave light (from reflected solar and electric lighting) that leave the zone through the window. This output variable is the term called “[Short-wave radiation from zone transmitted back out the window]” under the description above for Surface Window Heat Gain Rate output variable.

#### **1.10.47.77 Surface Window Inside Face Frame and Divider Zone Heat Gain Rate [W]**

This is the heat transfer from any frames and/or dividers to the zone in watts. This output variable is the term called “[Conduction to zone from window frame and divider, if present]” under the description above for Surface Window Heat Gain Rate output variable. (The word “conduction” here is used because the models is simplified compared to the complexities of surface convection and radiation.)

#### **1.10.47.78 Surface Window Frame Heat Gain Rate [W]**

This is the positive heat flow from window frames to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.10.47.79 Surface Window Frame Heat Loss Rate [W]**

This is the negative heat flow from window frames to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.10.47.80 Surface Window Frame Inside Temperature [C]**

This is the temperature of the inside surface of the window frames.

**1.10.47.81 Surface Window Frame Outside Temperature [C]**

This is the temperature of the outside surface of the window frames.

**1.10.47.82 Surface Window Divider Heat Gain Rate [W]**

This is the positive heat flow from window dividers to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

**1.10.47.83 Surface Window Divider Heat Loss Rate [W]**

This is the negative heat flow from window dividers to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

**1.10.47.84 Surface Window Divider Inside Temperature [C]**

This is the temperature of the inside surface of the window dividers.

**1.10.47.85 Surface Window Divider Outside Temperature [C]**

This is the temperature of the outside surface of the window dividers.

**1.10.47.86 Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate [W]**

This is the convection surface heat transfer from the both the glazing and the shade's back face to the zone in Watts. This output variable is the term called “[Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]” under the description above for Surface Window Heat Gain Rate output variable. For Equivalent Layer window this output variable is the convection heat gain from vented interior air gap to the zone in Watts.

**1.10.47.87 Surface Window Inside Face Shade Zone Convection Heat Gain Rate [W]**

This is the convection surface heat transfer from the front side of any interior shade or blind to the zone in Watts. This output variable is the term called “[Convective heat flow to the zone from the zone side of the shading device]” under the description above for Surface Window Heat Gain Rate output variable. For equivalent Layer window this output variable is the convection heat gain rate from the inside face of a glazing or a shade to the zone in Watts.

**1.10.47.88 Surface Window Inside Face Shade Net Infrared Heat Transfer Rate [W]**

The net exchange of infrared radiation heat transfer from the shade or blind to the zone in watts. This output variable is the term called “[Net IR heat flow to the zone from the zone side of the shading device]” under the description above for Surface Window Heat Gain Rate output variable.

**1.10.47.89 Surface Window Inside Face Other Convection Heat Gain Rate [W]**

The other (extra) convection heat transfer rate from the inside face of a an equivalent layer window. This output is computed from the difference in convection flux when using equivalent inside surface temperature of a window instead of the inside surface temperature from the standard surface heat balance calculation.

## 1.10.48 Thermochromic Window Outputs

### 1.10.48.1 Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

### 1.10.48.2 Surface Window Thermochromic Layer Property Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the **.eio** file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “\_TC\_XX” where XX represents a specification temperature.

### 1.10.48.3 Switchable Window Outputs

### 1.10.48.4 Surface Window Switchable Glazing Switching Factor[]

The switching factor (tint level) of the switchable window: 0 means no switching – clear state; 1 means fully switched – dark state.

### 1.10.48.5 Surface Window Switchable Glazing Visible Transmittance[]

The visible transmittance of the switchable window.

## 1.10.49 Other Surface Outputs/Reports

Several reports can be selected for Surfaces. (See Group – Report for details on how to specify). Examples are:

### 1.10.49.1 DXF

This report produces a special file (**eplusout.dxf**) in the industry standard DXF (Drawing Interchange Format) for drawings. It is produced and accepted by many popular, commercial CAD programs. Detailed reference can be found on the AutoCAD™ website at: <http://www.autodesk.com/techpubs/autocad/acadr14/dxf/index.htm>.

EnergyPlus produces this file from the Report command:

```
Output:Reports, Surfaces, DXF;
```

### 1.10.49.2 Details, Vertices, DetailsWithVertices

This version of the report creates lines in the **eplusout.eio** file for each surface (except internal mass surfaces). Details of this reporting is shown in the Output Details and Examples document.

## 1.10.50 Shading Surfaces

Shading surfaces are entities outside of the building that may cast shadows on the building's heat transfer surfaces. These entities do not typically have enough thermal mass to be described as part of the building's thermal makeup.

The most important effect of shading surfaces is to reduce solar gain in windows that are shadowed. (However, in some cases, shading surfaces can reflect solar onto a wall or window and increase solar gain.)

There are two kinds of shading surfaces in EnergyPlus: **detached** and **attached**. A **detached** shading surface, such as a tree or neighboring building, is not connected to the building. An **attached** shading surface is typically an overhang or fin that is attached to a particular base surface of the building, usually a wall; attached shading surfaces are usually designed to shade specific windows.

Objects for detached shading surfaces:

- Shading:Site
- Shading:Building
- Shading:Site:Detailed
- Shading:Building:Detailed

Similarly to the surfaces, the detailed objects use vertex entry whereas the other objects are limited to rectangular representation.

Objects for attached shading surfaces:

- Shading:Overhang
- Shading:Overhang:Projection
- Shading:Fin
- Shading:Fin:Projection
- Shading:Zone:Detailed

EnergyPlus creates “bi-directional” shades from each shading surface entered. This means that the shade you input will cast a shadow no matter which side of the shade the sun is on. For example, a vertical fin will cast a shadow whether the sun is on the left side or right side of the fin. Prior to V1.0.2, a shading surface cast a shadow only in the hemisphere toward which the surface faced. This hemisphere is the one pointed to by the shading surface’s outward normal vector, which is the cross product  $V23 \times V21$ , where  $V23$  is the vector from vertex 2 to vertex 3 of the shading surface and  $V21$  is the vector from vertex 2 to vertex 1. Beginning with V1.0.2, the shades in EnergyPlus are “bi-directional” so that they can cast shadows in both hemispheres depending on the time-varying position of the sun relative to the shading surface.

It is important to note that EnergyPlus will automatically account for “self-shading” effects—such as in L-shaped buildings—in which some of the building’s wall and roof surfaces shade other parts of the building, especially windows. This means that you only need to describe shading elements that aren’t building heat-transfer surfaces.

Shading surfaces can also **reflect** solar radiation onto the building. This feature is simulated if you choose **FullExteriorWithReflections** or **FullInteriorAndExteriorWithReflections** in the **Building** object (ref: **Building - Field: Solar Distribution**). In this case, you may specify the reflectance properties of a shading surface with the **ShadingProperty:Reflectance** object. Note: If no **ShadingProperty:Reflectance** object is defined, then the shading surface reflectance values are assumed to be 0.2 and the fraction of shading surface that is glazed is assumed to be 0.0.

Shading surfaces also automatically shade diffuse solar radiation (and long-wave radiation) from the sky. And they will automatically shade diffuse solar radiation from the ground if **Solar Distribution Field = FullExteriorWithReflections** or **FullInteriorAndExteriorWithReflections** in the **Building** object. (If

the reflections option for Solar Distribution is used, the program also takes into account the reduction of solar radiation reflected from the ground due to shading of the ground by shading surfaces and by the building itself.) Otherwise, shading surfaces will not shade diffuse radiation from the ground unless you enter a reduced value for View Factor to Ground for those building surfaces that are shaded (ref: [BuildingSurface:Detailed](#) - Field: View Factor to Ground and [FenestrationSurface:Detailed](#) - Field: View Factor to Ground).

### 1.10.51 Detached Shading Surfaces

### 1.10.52 Shading:Site, Shading:Building

These objects are used to describe rectangular shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in [GlobalGeometryRules](#)), shading surfaces entered with [Shading:Site](#) remain stationary if the building is rotated, whereas those entered with [Shading:Building](#) rotate with the building. If world coordinates are used [Shading:Site](#) and [Shading:Building](#) are equivalent.

These shading elements are always opaque.

#### 1.10.52.1 Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

#### 1.10.52.2 Field: Azimuth Angle

Theoretically, this should face to the surface it is shading (i.e. if a south wall, this should be a north facing shade) but since EnergyPlus automatically generates the mirror image, the facing angle per se' is not so important.

#### 1.10.52.3 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the shade is tilted from horizontal (or the ground). Default for this field is 90 degrees.

#### 1.10.52.4 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. See the introductory paragraph for rules on this entry.

#### 1.10.52.5 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.10.52.6 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.10.52.7 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.10.52.8 Field: Length

This field is the length of the shade in meters.

### 1.10.52.9 Field: Height

This field is the width of the shade in meters.

Examples of these (can be found in example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2.idf)

```

## 1.10.53 Shading:Site:Detailed, Shading:Building:Detailed

These objects are used to describe shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in [GlobalGeometryRules](#)), shading surfaces entered with **Shading:Site:Detailed** remain stationary if the building is rotated, whereas those entered with **Shading:Building:Detailed** rotate with the building. If world coordinates are used **Shading:Site:Detailed** and **Shading:Building:Detailed** are equivalent.

While “detached” implies that shading surfaces are not part of the building, the detached shading sequence can be used to describe attached shading surfaces that may shade heat transfer surfaces in more than one zone. For example, wing A of a building might shade several zones of wing B but wing A (for whatever reason) is not described in the geometry for the simulation so it is represented by a detached shade to get its shadowing effect.

### 1.10.53.1 Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

### 1.10.53.2 Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also

be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.
- For the daylighting calculation (ref: Group – Daylighting) the shading surface's visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

#### 1.10.53.3 Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

IDF example of Detached Shading Surfaces:

```

Shading:Building:Detailed,
  EAST SIDE TREE,  !- Detached Shading

```

#### 1.10.54 Attached Shading Surfaces

Overhangs are usually horizontal devices that are used to shade windows. Fins are usually vertical devices that similarly shade windows.

## 1.10.55 Shading:Overhang

An overhang typically is used to shade a window in a building.

### 1.10.55.1 Inputs

#### 1.10.55.1.1 Field: Name

This is the name of the overhang. It must be different from other surface names.

#### 1.10.55.1.2 Field: Window or Door Name

The name of a window or door that this overhang shades.

#### 1.10.55.1.3 Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

#### 1.10.55.1.4 Field Tilt Angle from Window/Door

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

#### 1.10.55.1.5 Field: Left Extension from Window/Door Width

This field is the width from the left edge of the window/door to the start of the overhang (meters).

#### 1.10.55.1.6 Field: Right Extension from Window/Door Width

This field is the width from the right edge of the window/door to the start of the overhang (meters).

#### 1.10.55.1.7 Field: Depth

This field is the depth of the overhang (meters) projecting out from the wall.

## 1.10.56 Shading:Overhang:Projection

An overhang typically is used to shade a window in a building. This object allows for specifying the depth of the overhang as a fraction of the window or door's height.

### 1.10.56.1 Inputs

#### 1.10.56.1.1 Field: Name

This is the name of the overhang. It must be different from other surface names.

#### 1.10.56.1.2 Field: Window or Door Name

The name of a window or door that this overhang shades.

#### 1.10.56.1.3 Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

#### 1.10.56.1.4 Field Tilt Angle from Window/Door

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

#### 1.10.56.1.5 Field: Left Extension from Window/Door Width

This field is the width from the left edge of the window/door to the start of the overhang (meters).

**1.10.56.1.6 Field: Right Extension from Window/Door Width**

This field is the width from the right edge of the window/door to the start of the overhang (meters).

**1.10.56.1.7 Field: Depth as Fraction of Window/Door Height**

This field is the fraction of the window/door height to specify as the depth of the overhang (meters) projecting out from the wall.

**1.10.57 Shading:Fin**

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. Fin placement is relative to the edge of the glass and user must include the frame width when a frame is present.

**1.10.57.1 Inputs****1.10.57.1.1 Field: Name**

This is the name of the fin. It must be different from other surface names.

**1.10.57.1.2 Field: Window or Door Name**

The name of a window or door that this fin shades.

**1.10.57.1.3 Field: Left Fin Extension from Window/Door**

This field is the width from the left edge of the window/door to the plane of the left fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

**1.10.57.1.4 Field: Left Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

**1.10.57.1.5 Field: Left Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

**1.10.57.1.6 Field: Left Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

**1.10.57.1.7 Field: Left Fin Depth**

This field is the depth (meters) of the left fin (projecting out from the wall).

**1.10.57.1.8 Field: Right Fin Extension from Window/Door**

This field is the width from the right edge of the window/door to the plane of the right fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

**1.10.57.1.9 Field: Right Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

### **1.10.57.1.10 Field: Right Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the right fin (meters) and is relative to the edge of the glass and includes the frame width.

### **1.10.57.1.11 Field: Right Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the right fin. Typically, a fin is 90 degrees (default) from its associated window/door.

### **1.10.57.1.12 Field: Right Fin Depth**

This field is the depth (meters) of the right fin (projecting out from the wall).

## **1.10.58 Shading:Fin:Projection**

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. This object allows for specifying the depth of the fin as a fraction of the window or door's width. Fin placement is relative to the edge of the glass and user must include the frame width when a frame is present.

### **1.10.58.1 Inputs**

#### **1.10.58.1.1 Field: Name**

This is the name of the fin. It must be different from other surface names.

#### **1.10.58.1.2 Field: Window or Door Name**

The name of a window or door that this fin shades.

#### **1.10.58.1.3 Field: Left Fin Extension from Window/Door**

This field is the width from the left edge of the window/door to the plane of the left fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.10.58.1.4 Field: Left Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.10.58.1.5 Field: Left Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.10.58.1.6 Field: Left Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

#### **1.10.58.1.7 Field: Left Fin Depth as Fraction of Window/Door Width**

This field is the fraction of the window/door width to specify as the depth of the left fin (meters) projecting out from the wall.

#### 1.10.58.1.8 Field: Right Fin Extension from Window/Door

This field is the width from the right edge of the window/door to the plane of the right fin (meters).. The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### 1.10.58.1.9 Field: Right Fin Distance Above Top of Window

This field is the distance from the top of the window to the top of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### 1.10.58.1.10 Field: Right Fin Distance Below Bottom of Window

This field is the distance from the bottom of the window to the bottom of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### 1.10.58.1.11 Field: Right Fin Tilt Angle from Window/Door

This field is the tilt angle from the window / door for the right fin. Typically, a fin is 90 degrees (default) from its associated window/door.

#### 1.10.58.1.12 Field: Right Fin Depth as Fraction of Window/Door Width

This field is the fraction of the window/door width to specify as the depth of the right fin (meters) projecting out from the wall.

Examples of these (can be found in example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2.idf)

```

### 1.10.59 Shading:Zone:Detailed

This object is used to describe attached “subsurfaces” such as overhangs, wings or fins that project outward from a base surface. This classification is used for convenience; actually, a device of this type can cast shadows on the surface to which it is attached as well as on adjacent surfaces. For example, a fin may shade its parent wall as well as adjacent walls.

Note that a zone surface can cast shadows on other zone surfaces. However, you don’t have to worry about such effects—for example, one wall of an L-shaped building shading another wall—because EnergyPlus will automatically check for this kind of “self shadowing” and do the proper calculations.

Unlike attached (or detached) shading surfaces, building surfaces can only cast shadows in the hemisphere towards which they face. This means, for example, that a roof that faces *upward* will not cast a shadow *downward*. (Thus, specifying an oversized roof in an attempt to account for the shading effects of overhangs will *not* work). Interior surfaces do not cast shadows of any kind.

#### 1.10.59.1 Inputs

##### 1.10.59.1.1 Field: Name

This is the name of the attached shading surface. It must be different from other surface names.

##### 1.10.59.1.2 Field: Base Surface Name

This is the name of the surface to which this shading device is attached. This surface can be a wall (or roof) but not a window or door.

##### 1.10.59.1.3 Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.
- For the daylighting calculation (ref: Group – Daylighting) the shading surface’s visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

#### 1.10.59.1.4 Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above. The example below shows the correct input for an overhang (to shade the appropriate portion of the base wall and window).

Proper specification for this overhang (facing up) is:

4,(C,0,D),(C,-B,D),(C+A,-B,D),(C+A,0,D); () used to illustrate each vertex.

Note that for horizontal surfaces, any corner may be chosen as the starting corner. The order of vertices determines whether the surface is facing up or down. Shading surfaces are mirrored automatically unless the user specifies “DoNotMirrorDetachedShading”, so each shading surface need only be described once.

Thus, another shading surface will be created (facing down):

4,(C+A,-B,D),(C+A,0,D),(C,0,D),(C,-B,D);

IDF example of attached shading surfaces (overhang, fin):

```

```

#### 1.10.60 ShadingProperty:Reflectance

Specifies the reflectance properties of a shading surface when the solar reflection calculation has requested, i.e., when if “WithReflections” option is chosen in the Building object (ref: Building - Field: Solar Distribution). It is assumed that shading surfaces are divided into an unglazed, diffusely reflecting portion

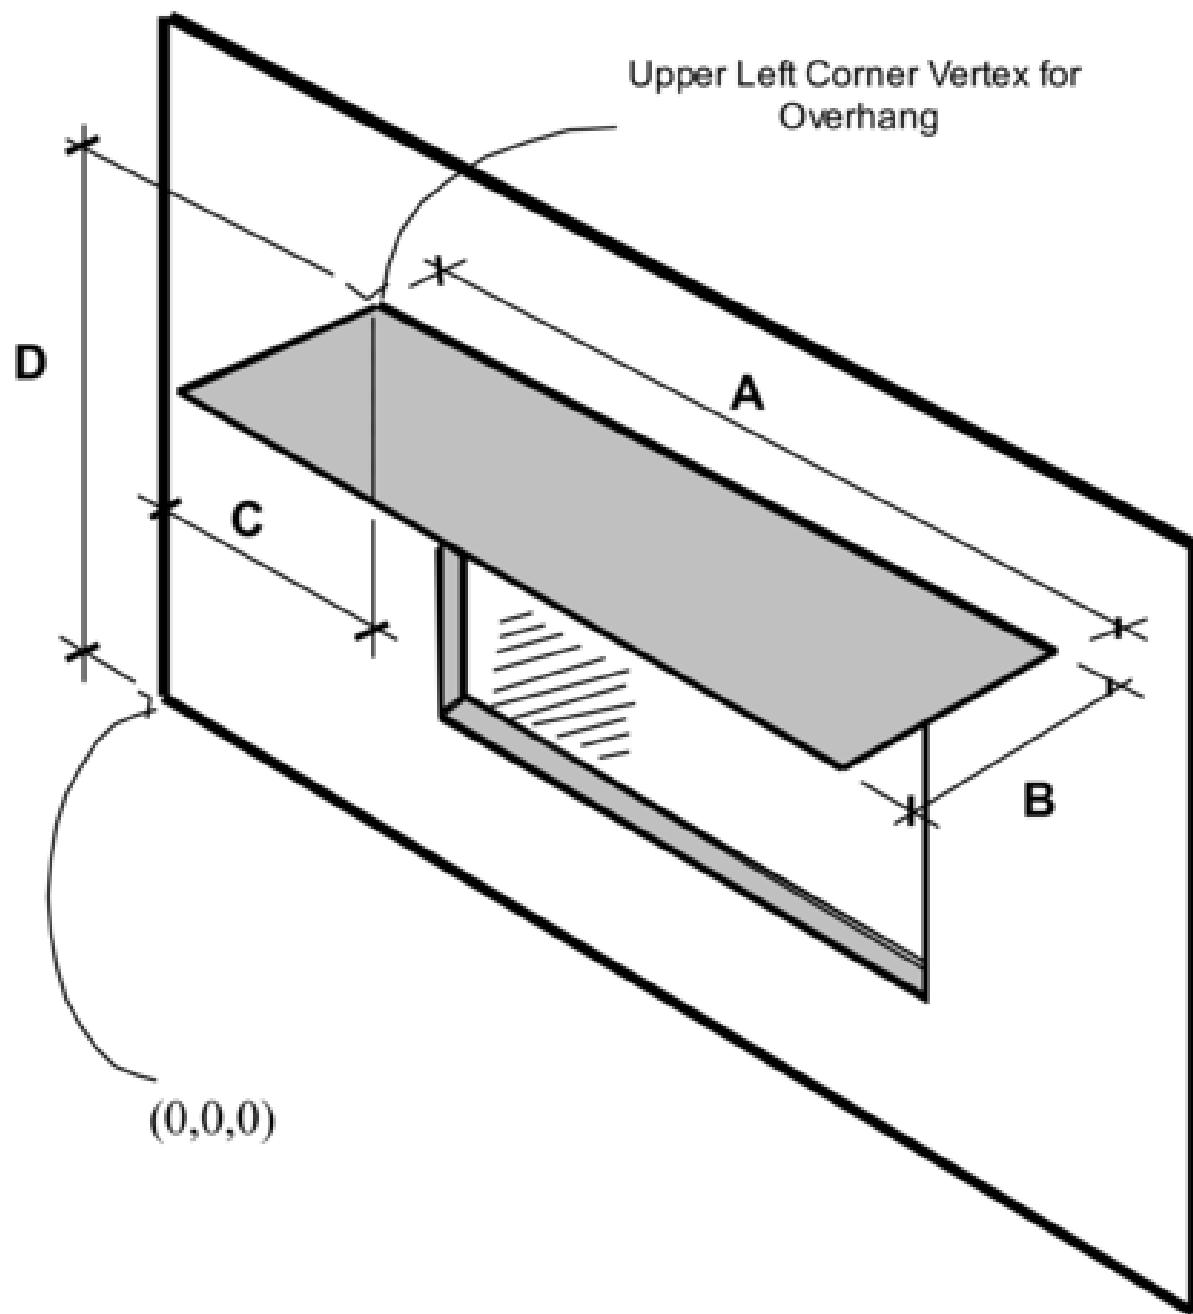

Figure 1.35: Illustration for Attached Shading Surface

and a glazed, specularly-reflecting portion, either of which may be zero. The reflectance properties are assumed to be the same on both sides of the shading surface.

Note that a shadowing transmittance schedule (ref: Shading Surfaces, Field: Transmittance Schedule Name) can be used with a reflective shading surface. However, EnergyPlus assumes that the reflectance properties of the shading surface are constant even if the transmittance varies.

If no ShadingProperty:Reflectance objects are entered, the default values shown here will be used for shading surfaces. Other surfaces have their reflectance properties defined by the materials in the outer layers of the constructions.

### 1.10.60.1 Inputs

#### 1.10.60.1.1 Field: Shading Surface Name

The name of the [Shading:Site](#), [Shading:Building](#), [Shading:Site:Detailed](#), [Shading:Building:Detailed](#), [Shading:Overhang](#), [Shading:Overhang:Projection](#), [Shading:Fin](#), [Shading:Fin:Projection](#) or [Shading:Zone:Detailed](#) object to which the following fields apply.

If this ShadingProperty:Reflectance object is not defined for a shading surface the default values listed in each of the following fields will be used in the solar reflection calculation.

#### 1.10.60.1.2 Field: Diffuse Solar Reflectance of Unglazed Part of Shading Surface

The diffuse solar reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

#### 1.10.60.1.3 Field: Diffuse Visible Reflectance of Unglazed Part of Shading Surface

The diffuse visible reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

This value if used only for the daylighting calculation (ref: [Daylighting:Controls](#)). The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

#### 1.10.60.1.4 Field: Fraction of Shading Surface That Is Glazed

The fraction of the area of the shading surface that consists of windows (default = 0.0). It is assumed that the windows are evenly distributed over the surface and have the same glazing construction (see following “Name of Glazing Construction”). This might be the case, for example, for reflection from the façade of a neighboring, highly-glazed building. For the reflection calculation the possible presence of shades, screens or blinds on the windows of the shading surface is ignored. Beam-to-beam (specular) reflection is assumed to occur only from the glazed portion of the shading surface. This reflection depends on angle of incidence as determined by the program from the glazing construction. Beam-to-diffuse reflection from the glazed portion is assumed to be zero. The diffuse-to-diffuse reflectance of the glazed portion is determined by the program from the glazing construction.

#### 1.10.60.1.5 Field: Glazing Construction Name

The name of the construction of the windows on the shading surface. Required if Fraction of Shading Surface That Is Glazed is greater than 0.0.

IDF example of Shading Surface Reflectance for shading surface with specular reflection

```

## 1.10.61 WindowShadingControl

Window shading with coverings like drapes, blinds, screens or pull-down shades can be used to reduce the amount of solar radiation entering the window or reduce daylighting glare. It can also be used to reduce heat loss through the window (movable insulation). Leaving the window covering open in the winter can maximize solar heat gain and thereby reduce heating loads.

With WindowShadingControl you specify the type, location, and timing of the shading device, what variable or combination of variables controls deployment of the shading device, and what the control setpoint is. If the shading device is a blind, you also specify how the slat angle is controlled. Each WindowShadingControl object is associated with a zone and has a list of one or more windows and glass doors to which the shading control is applied (ref: [FenestrationSurface:Detailed](#) with Type = Window or GlassDoor, Window, and [GlazedDoor](#)).

NOTE: WindowShadingControl does not work with complex fenestration systems. Controlled complex fenestration systems can be made only with Energy Management Systems objects. Refrencing a [FenestrationSurface:Detailed](#) in a WindowShadingControl while using complex fenestration systems will be ignored by program.

As shown in Figure 1.36, a shading device can be inside the window (Shading Type = InteriorShade or InteriorBlind), outside the window (Shading Type = ExteriorShade or ExteriorBlind), or between panes of glass (Shading Type = BetweenGlassShade or BetweenGlassBlind). The exception is window screens which can only be outside the window (Shading Type = ExteriorScreen).

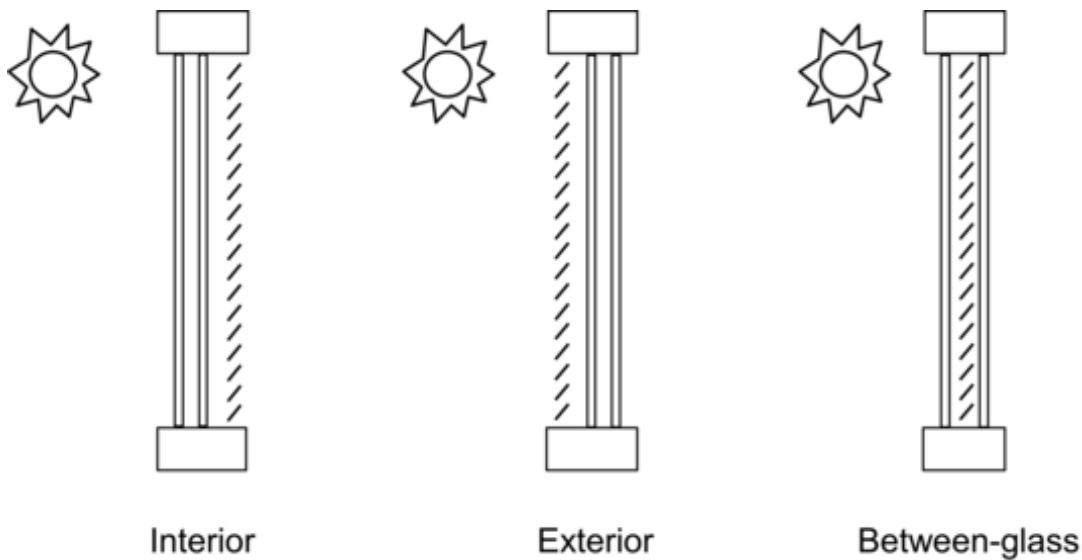

Figure 1.36: Allowed locations of a window shading device.

When a shading device is present it is either retracted or activated. When it is retracted it covers none of the window. When it is activated it covers the entire glazed part of the window (but not the frame). Whether the shading device is retracted or activated in a particular timestep depends on the control mechanism: see “Shading Control Type,” below. To model a case in which the shading device, when activated, covers only **part** of the window you will have to divide the window into two separate windows, one with the shading device and one without the shading device.

A shading device can also be of a kind in which the optical properties of the glazing switch from one set of values to another in order to increase or decrease solar or visible transmittance (Shading Type = SwitchableGlazing).

There are two ways of specifying the actual shading device:

- **Specify “Name of Construction with Shading”**

This is the name of a window Construction that has the shading device as one of its layers. The thermal and solar-optical properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, [WindowMaterial:Shade](#), [WindowMaterial:Screen](#) and [WindowMaterial:Blind](#)). To use this method you have to define two Constructions for the window, one without the shading device and one with it. See Example 1, below.

The Construction without the shading device is referenced in the [FenestrationSurface:Detailed](#) input for the window (see IDF example, below). The Construction with the shading device is referenced by the window’s WindowShadingControl.

For Shading Type = InteriorShade, InteriorBlind, ExteriorShade, ExteriorScreen and ExteriorBlind these two Constructions must be identical except for the presence of the shading layer in the shaded Construction, otherwise you will get an error message. You will also get an error message if the Construction referenced by the window has a shading layer.

- **Specify the “Material Name of the Shading Device”**

This is the name of a [WindowMaterial:Shade](#), [WindowMaterial:Screen](#) or [WindowMaterial:Blind](#). This method can be used with Shading Type = InteriorShade, InteriorBlind, ExteriorShade and ExteriorBlind. It cannot be used with Shading Type = BetweenGlassShade, BetweenGlassBlind, or

`SwitchableGlazing`. If Shading Type = `InteriorShade` or `ExteriorShade`, then you specify the name of a `WindowMaterial:Shade`. If Shading Type = `InteriorBlind` or `ExteriorBlind`, then you specify the name of a `WindowMaterial:Blind`. If Shading Type = `ExteriorScreen`, then you specify the name of a `WindowMaterial:Screen`. See Example 2, below. This method is simpler to use since you don't have to specify two Constructions that differ only by the shading layer.

When this method is used, the program will automatically create a shaded window construction by adding a shading layer to the outside or inside of the construction corresponding to the windows referenced by the `WindowShadingControl`. The name, created by the program, of this shaded construction is composed as follows: if the name of the window construction is CCC and the material name of the shading device is DDD, then the shaded construction name is CCC:DDD:INT for an interior shading device and CCC:DDD:EXT for an exterior shading device.

This method is the required if you want to add a shading device to a construction brought in from a `WINDOW` Data File (ref:[Construction:WindowDataFile](#)).

Note that if both "Name of Construction with Shading" and "Material Name of Shading Device" are specified, the former takes precedence.

Most Shading Control Types allow you to specify a schedule that determines when the control is active. One example is a control that is active seasonally. For example, to deploy shading only in the summer when the incident solar is high enough, use Shading Control Type = `OnIfHighSolarOnWindow` with a schedule that is 1 during the summer months and 0 otherwise and specify `Shading Control Is Scheduled` = YES.

To deploy one shading device during one time period and another during another time period for the same window, specify two different `WindowShadingControl` objects that both reference the same fenestration. Each of the `WindowShadingControl` input objects would include the same window on their lists of fenestration objects, but would reference different schedule input objects. The referenced schedule input objects should have non-zero values specified at different times for each `WindowShadingControl`. This approach can be used to add shading that is different for different seasons. When more than one `WindowShadingControl` is used for the same window based on schedule, the type of shading, control type, setpoints, and several other parameters must be the same in the different `WindowShadingControl` objects, but the shading device and construction can be different.

In addition, most Shading Control Types also allow you to specify that glare control is active in addition to the specified Control Type. For example, you might want to deploy shading when the solar incident on a window is too high OR the glare from the window is too high. This type of joint control requires that the window be in a daylit zone, that the maximum allowed glare be specified in the Daylighting object for the zone, and that `Glare Control Is Active` = YES in `WindowShadingControl`.

If Shading Type = `InteriorBlind`, `ExteriorBlind` or `BetweenGlassBlind` you can use `WindowShadingControl` to specify how the slat angle of the blind is controlled when the blind is in place.

A special type of `WindowShadingControl` is `SwitchableGlazing`. An example is electrochromic glazing in which the transmittance and reflectance of the glass is controlled electronically. For example, you could have electrochromic glazing switch from clear (high transmittance) to dark (low transmittance) to control solar gain. If you choose the Shading Type = `SwitchableGlazing` option for `WindowShadingControl`, the unswitched (clear) state is specified by the Construction referenced by the window and the switched (dark) state is specified by the Construction referenced by `WindowShadingControl` for that window. For example, if you specify Shading Type = `SwitchableGlazing` and Shading Control Type = `OnIfHighSolarOnWindow`, then the glazing will switch to the dark state whenever the solar radiation striking the window exceeds the Setpoint value.

For Shading Type = `SwitchableGlazing` the state of the window is either clear (unswitched) or dark (fully switched) for all Shading Control Types except `MeetDaylightIlluminanceSetpoint`. In this case,

the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point (see Daylighting). This type of control assures that there is just enough solar gain to meet the daylighting requirements in a zone, and no more, thus reducing the cooling load.

To specify the order of when shades are deployed, the two different approaches can be used:

- If shades for each window are independently controlled, than a single WindowShadingControl object should be used and the Multiple Surface Control Type field should be set to Sequential. The windows should be specified in the Fenestration Surface N Name fields in the order that they should be deployed. The Shading Control Sequence Number field is not used being used since only one WindowShadingControl is used so it can be set to any value or left blank.

- If shades for a group of windows are deployed together and shades for another group of windows are deployed after that, than multiple WindowShadingControl objects should be used. Each WindowShadingControl should have Multiple Surface Control Type field should be set to Group and the names of each window in the group should be specified in the Fenestration Surface N Name fields. The Shading Control Sequence Number in the WindowShadingControl object that controls the first group of shades should be set to 1. The Shading Control Sequence Number in the WindowShadingControl object that controls the second group of shades should be set to 2. Any number of additional groups of shades can be added and Shading Control Sequence Number can be incremented by one for each group.

It is possible to mix these two approaches. For example, if first a group of shades is controlled together followed by a sequence of individual windows than these approaches can be combined with the Multiple Surface Control Type field should be set to Sequential in the second WindowShadingControl object.

### 1.10.61.1 Inputs

#### 1.10.61.1.1 Field: Name

Name of the window shading control.

#### 1.10.61.1.2 Field: Zone Name

Name of the zone where this shading control is used.

#### 1.10.61.1.3 Field: Shading Control Sequence Number

If multiple WindowShadingControl objects are used in the same zone, then the order that they deploy the window shades can be set with this field. The first WindowShadingControl should be 1 and subsequent WindowShadingControl should 2, 3, etc. This is usually used when the Multiple Surface Control Type field is set to Group to control groups of windows in a certain order.

#### 1.10.61.1.4 Field: Shading Type

The type of shading device. The choices are:

*InteriorShade*: A diffusing shade is on the inside of the window. (In the shaded Construction the shading layer must be a **WindowMaterial:Shade**.)

*ExteriorShade*: A diffusing shade is on the outside of the window. (In the shaded Construction the shading layer must be a **WindowMaterial:Shade**.)

*BetweenGlassShade*: A diffusing shade is between two glass layers. (In the shaded Construction the shading layer must be a **WindowMaterial:Shade**.) This shading type is allowed only for double- and triple-glazing. For triple-glazing the shade must be between the two inner glass layers.

*ExteriorScreen*: An insect screen is on the outside of the window. (In the shaded Construction the shading layer must be a **WindowMaterial:Screen**.)

*InteriorBlind*: A slat-type shading device, such as a Venetian blind, is on the inside of the window. (In the shaded Construction the shading layer must be a **WindowMaterial:Blind**.)

*ExteriorBlind*: A slat-type shading device is on the outside of the window. (In the shaded Construction the shading layer must be a [WindowMaterial:Blind](#).)

*BetweenGlassBlind*: A slat-type shading device is between two glass layers. (In the shaded Construction the shading layer must be a [WindowMaterial:Blind](#).) This shading type is allowed only for double- and triple-glazing. For triple-glazing the blind must be between the two inner glass layers.

*SwitchableGlazing*: Shading is achieved by changing the characteristics of the window glass, such as by darkening it.

#### 1.10.61.1.5 Field: Construction with Shading Name

Name of the window Construction that has the shading in place. The properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, [WindowMaterial:Shade](#), [WindowMaterial:Screen](#) and [WindowMaterial:Blind](#)). For Shading Type = SwitchableGlazing, this is the name of the Construction that corresponds to the window in its fully-switched (darkest) state.

Specifying “Name of Construction with Shading” is required if Shading Type = BetweenGlassShade, BetweenGlassBlind, or SwitchableGlazing. For other Shading Types, you may alternatively specify “Material Name of Shading Device” (see below).

#### 1.10.61.1.6 Field: Shading Control Type

Specifies how the shading device is controlled, i.e., it determines whether the shading device is “on” or “off.” For blinds, screens and shades, when the device is “on” it is assumed to cover all of the window except its frame; when the device is “off” it is assumed to cover none of the window (whether “on” or “off” the shading device is assumed to cover none of the wall that the window is on).

For switchable glazing, “on” means that the glazing is in the fully-switched state and “off” means that it is in the unswitched state; for example, for electrochromic glazing, “on” means the glazing is in its darkest state and “off” means it is in its lightest state.

The choices for Shading Control Type are the following. If SetPoint is applicable its units are shown in parentheses.

*AlwaysOn*: Shading is always on.

*AlwaysOff*: Shading is always off.

The following six control types are used primarily to reduce zone cooling load due to window solar gain.

*OnIfScheduleAllows*: Shading is on if schedule value is non-zero. Requires that Schedule Name be specified and Shading Control Is Scheduled = Yes.

Note: For exterior window screens *AlwaysOn*, *AlwaysOff*, and *OnIfScheduleAllows* are the only valid shading control types.

*OnIfHighSolarOnWindow*: Shading is on if beam plus diffuse solar radiation incident on the window exceeds SetPoint ( $\text{W/m}^2$ ) and schedule, if specified, allows shading.

*OnIfHighHorizontalSolar*: Shading is on if total (beam plus diffuse) horizontal solar irradiance exceeds SetPoint ( $\text{W/m}^2$ ) and schedule, if specified, allows shading.

*OnIfHighOutdoorAirTemperature*: Shading is on if outside air temperature exceeds SetPoint (C) and schedule, if specified, allows shading.

*OnIfHighZoneAirTemperature*: Shading is on if zone air temperature in the previous timestep exceeds SetPoint (C) and schedule, if specified, allows shading.

*OnIfHighZoneCooling*: Shading is on if zone cooling rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading.

*OnIfHighGlare*: Shading is on if the total daylight glare index at the zone’s first daylighting reference point from all of the exterior windows in the zone exceeds the maximum glare index specified in the

daylighting input for zone (ref: Group – Daylighting). Applicable only to windows in zones with daylighting.

Note: Unlike other Shading Control Types, glare control is active whether or not a schedule is specified.

*MeetDaylightIlluminanceSetpoint:* Used only with ShadingType = SwitchableGlazing in zones with daylighting controls. In this case the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point. Note that the daylight illuminance set point is specified in the **Daylighting:Controls** object for the Zone; it is not specified as a WindowShadingControl SetPoint. When the glare control is active, if meeting the daylight illuminance set point at the first daylighting reference point results in higher discomfort glare index (DGI) than the specified zone's maximum allowable DGI for either of the daylight reference points, the glazing will be further dimmed until the DGI equals the specified maximum allowable value.

The following three control types can be used to reduce zone heating load during the winter by reducing window conductive heat loss at night and leaving the window unshaded during the day to maximize solar gain. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior shades with high insulating value (“movable insulation”). “Night” means the sun is down and “day” means the sun is up.

*OnNightIfLowOutdoorTempAndOffDay:* Shading is on at night if the outside air temperature is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

*OnNightIfLowInsideTempAndOffDay:* Shading is on at night if the zone air temperature in the previous timestep is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

*OnNightIfHeatingAndOffDay:* Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading. Shading is off during the day.

The following two control types can be used to reduce zone heating and cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for translucent interior or exterior shades with high insulating value (“translucent movable insulation”).

*OnNightIfLowOutdoorTempAndOnDayIfCooling:* Shading is on at night if the outside air temperature is less than SetPoint (C). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

*OnNightIfHeatingAndOnDayIfCooling:* Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

The following control types can be used to reduce zone cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior blinds, interior or exterior shades with low insulating value, or switchable glazing.

*OffNightAndOnDayIfCoolingAndHighSolarOnWindow:* Shading is off at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint ( $\text{W/m}^2$ ) and if the zone cooling rate in the previous timestep is non-zero. Daytime shading is subject to schedule, if specified.

*OnNightAndOnDayIfCoolingAndHighSolarOnWindow:* Shading is on at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint ( $\text{W/m}^2$ ) and if the zone cooling rate in the previous timestep is non-zero. Day and night shading is subject to schedule, if specified. (This Shading Control Type is the same as the previous one, except the shading is on at night rather than off.)

*OnIfHighOutdoorAirTempAndHighSolarOnWindow:* Shading is on if the outside air temperature exceeds the Setpoint (C) and if the solar radiation incident on the window exceeds SetPoint 2 ( $\text{W/m}^2$ ).

*OnIfHighOutdoorAirTempAndHighHorizontalSolar:* Shading is on if the outside air temperature exceeds the Setpoint (C) and if the horizontal solar radiation exceeds SetPoint 2 ( $\text{W/m}^2$ ).

*OnIfHighZoneAirTempAndHighSolarOnWindow:* Shading is on if the zone air temperature exceeds the Setpoint (C) and if the solar radiation incident on the window exceeds SetPoint 2 ( $\text{W/m}^2$ ).

*OnIfHighZoneAirTempAndHighHorizontalSolar:* Shading is on if the zone air temperature exceeds the Setpoint (C) and if the horizontal solar radiation exceeds SetPoint 2 ( $\text{W/m}^2$ ).

### 1.10.61.1.7 Field: Schedule Name

Required if Shading Control Is Scheduled = Yes. If schedule value > 0 , shading control is active, i.e., shading can be on only if the shading control test passes. If schedule value = 0, shading is off whether or not the control test passes. If Schedule Name is not specified, shading control is assumed to be active at all times.

### 1.10.61.1.8 Field: Setpoint

The setpoint for activating window shading. The units depend on the type of trigger:

- W/m<sup>2</sup> for solar-based controls
- W for cooling- or heating-based controls
- Degrees C for temperature-based controls

SetPoint is unused for Shading Control Type = OnIfScheduleAllows, OnIfHighGlare and DaylightIlluminance.

### 1.10.61.1.9 Field: Shading Control Is Scheduled

Accepts values YES and NO. The default is NO. Not applicable for Shading Control Type = OnIfHighGlare and should be blank in that case.

If YES, Schedule Name is required and that schedule determines whether the shading control specified by Shading Control Type is active or inactive (see Schedule Name, above).

If NO, Schedule Name is not applicable (should be blank) and the shading control is unscheduled.

Shading Control Is Scheduled = YES is required if Shading Control Type = OnIfScheduleAllows.

### 1.10.61.1.10 Field: Glare Control Is Active

Accepts values YES and NO. The default is NO.

If YES and the window is in a daylit zone, shading is on if the zone's discomfort glare index exceeds the maximum discomfort glare index specified in the Daylighting object referenced by the zone. For switchable windows with *MeetDaylightIlluminanceSetpoint* shading control, if Glare Control is active, the windows are always continuously dimmed as necessary to meet the zone's maximum allowable DGI while providing appropriate amount of daylight for the zone.

The glare test is OR'ed with the test specified by Shading Control Type. For example, if Glare Control Is Active = YES and Shading Control Type = OnIfHighZoneAirTemp, then shading is on if glare is too high OR if the zone air temperature is too high.

Glare Control Is Active = YES is required if Shading Control Type = OnIfHighGlare.

### 1.10.61.1.11 Field: Shading Device Material Name

The name of a *WindowMaterial:Shade*, *WindowMaterial:Screen* or *WindowMaterial:Blind*. Required if “Name of Construction with Shading” is not specified. Not applicable if Shading Type = BetweenGlassShade, BetweenGlassBlind or SwitchableGlazing and should be blank in this case. If both “Name of Construction with Shading” and “Material Name of Shading Device” are entered the former takes precedence.

### 1.10.61.1.12 Field: Type of Slat Angle Control for Blinds

Applies only to Shading Type = InteriorBlind, ExteriorBlind or BetweenGlassBlind. Specifies how the slat angle is controlled. The choices are FixedSlatAngle, ScheduledSlatAngle and BlockBeamSolar.

If FixedSlatAngle (the default), the angle of the slat is fixed at the value input for the **WindowMaterial:Blind** that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device.

If ScheduledSlatAngle, the slat angle varies according to the schedule specified by Slat Angle Schedule Name, below.

If BlockBeamSolar, the slat angle is set each timestep to just block beam solar radiation. If there is no beam solar on the window the slat angle is set to the value input for the **WindowMaterial:Blind** that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device. The BlockBeamSolar option prevents beam solar from entering the window and causing possible unwanted glare if the beam falls on work surfaces while at the same time allowing near-optimal indirect radiation for daylighting.

### 1.10.61.1.13 Field: Slat Angle Schedule Name

This is the name of a schedule of slat angles that is used when Type of Slat Angle Control for Blinds = ScheduledSlatAngle. You should be sure that the schedule values fall within the range given by the Minimum Slat Angle and Maximum Slat Angle values entered in the corresponding **WindowMaterial:Blind**. If not, the program will force them into this range.

### 1.10.61.1.14 Field: Setpoint 2

Used only as the second setpoint for the following setpoint control types: OnIfHighOutdoorAirTempAndHighSolarOnWindow, OnIfHighOutdoorAirTempAndHighHorizontalSolar, OnIfHighZoneAirTempAndHighSolarOnWindow, and OnIfHighZoneAirTempAndHighHorizontalSolar

### 1.10.61.1.15 Field: Daylighting Controls Object Name

Name of the **Daylighting:Controls** object that provides the glare and illuminance control to the zone.

### 1.10.61.1.16 Field: Multiple Surface Control Type

The field can have one of two options:

*Sequential*: The following list of fenestration surfaces are controlled individually in the order specified.

*Group*: The entire list of fenestration surfaces is controlled simultaneously, and if glare control is needed, the entire group of window shades are deployed together at the same time.

### 1.10.61.1.17 Field: Fenestration Surface <n> Name

The name of a **FenestrationSurface:Detailed**, Window, or **GlazedDoor** object controlled by this WindowShadingControl. This field can be repeated to apply the same shading control to more than one fenestration surface. When Multiple Surface Control Type is set to Sequential, the order of the Fenestration Surface Names is the order that the shades will be deployed. The object is extensible so additional fields of fenestration surface names can be added to the object. All of the fenestration surfaces must be either in the zone specified in the Zone Name field or in an adjacent zone connected by an interior window.

An IDF example: window with interior roll shade that is deployed when solar incident on the window exceeds 50 W/m<sup>2</sup>.

## 1.10.62 WindowProperty:FrameAndDivider

The WindowProperty:FrameAndDivider object is referenced by exterior windows that have

- a frame, and/or
- a divider, and/or
- reveal surfaces that reflect beam solar radiation.

A **frame** surrounds the glazing in a window (see Figure 1.37 and Figure 1.38). It is assumed that all frame characteristics—such as width, conductance and solar absorptance—are the same for the top, bottom and side elements of the frame. If the frame elements are not the same then you should enter area-weighted average values for the frame characteristics.

The window vertices that you specify in the FenestrationSurface:Detailed object are those of the glazed part of the window, not the frame. EnergyPlus automatically subtracts the area of the frame—determined from the glazing dimensions and the frame width—from the area of the wall containing the window.

A **divider**, as shown in Figure 1.37, Figure 1.38 and Figure 1.39, divides the glazing up into separate lites. It is assumed that all divider elements have the same characteristics. If not, area-weighted average values should be used. EnergyPlus automatically subtracts the divider area from the glazed area of the window.

**Reveal surfaces**, as shown in Figure 1.40, are associated with the setback of the glazing from the outside and/or inside surface of the parent wall. If the depth and solar absorptance of these surfaces are specified, the program will calculate the reflection of beam solar radiation from these surfaces. The program also calculates the shadowing (onto the window) of beam and diffuse solar radiation by outside reveal surfaces.

In EnergyPlus, a window can have any combination of frame, divider and reveal surfaces, or none of these.

The best source of frame and divider characteristics is the WINDOW program, which will calculate the values required by EnergyPlus for different frame and divider types. In particular, the THERM program within the WINDOW program will calculate the effective conductance of frames and dividers; this is the conductance taking 2-D heat transfer effects into account.

Note that a window's frame and divider characteristics, along with other window information, can be read in from the Window Data File (see “Importing Windows from the WINDOW program” and “Construction:WindowDataFile object”). In this case the WindowProperty:FrameAndDivider referenced by the window is not applicable and should be blank unless you want to specify reveal surfaces for beam solar reflection.

In the illustration above, the divider has two horizontal elements and one vertical element.

### 1.10.62.1 Inputs

#### 1.10.62.1.1 Field: Name

The name of the frame/divider object. It is referenced by WindowProperty:FrameAndDivider Name in FenestrationSurface:Detailed.

##### *Frame Fields*

#### 1.10.62.1.2 Field: Frame Width

The width of the frame elements when projected onto the plane of the window. It is assumed that the top, bottom and side elements of the frame have the same width. If not, an average frame width should be entered such that the projected frame area calculated using the average value equals the sum of the areas of the frame elements.

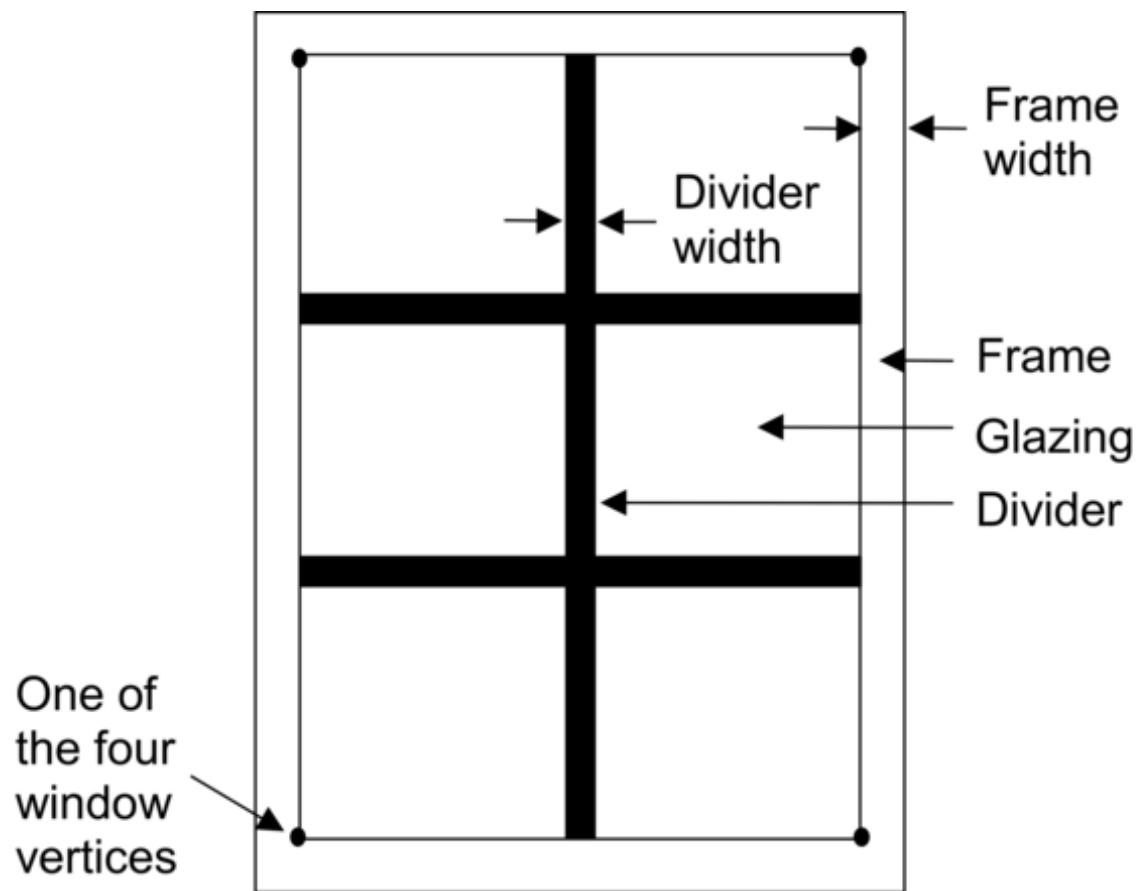

Figure 1.37: A window with a frame and divider.

### 1.10.62.1.3 Field: Frame Outside Projection

The amount by which the frame projects outward from the outside surface of the window glazing. If the outer surface of the frame is flush with the glazing, Frame Outside Projection = 0.0. Used to calculate shadowing of frame onto glass, solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

### 1.10.62.1.4 Field: Frame Inside Projection

The amount by which the frame projects inward from the inside surface of the window glazing. If the inner surface of the frame is flush with the glazing, Frame Inside Projection = 0.0. Used to calculate solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

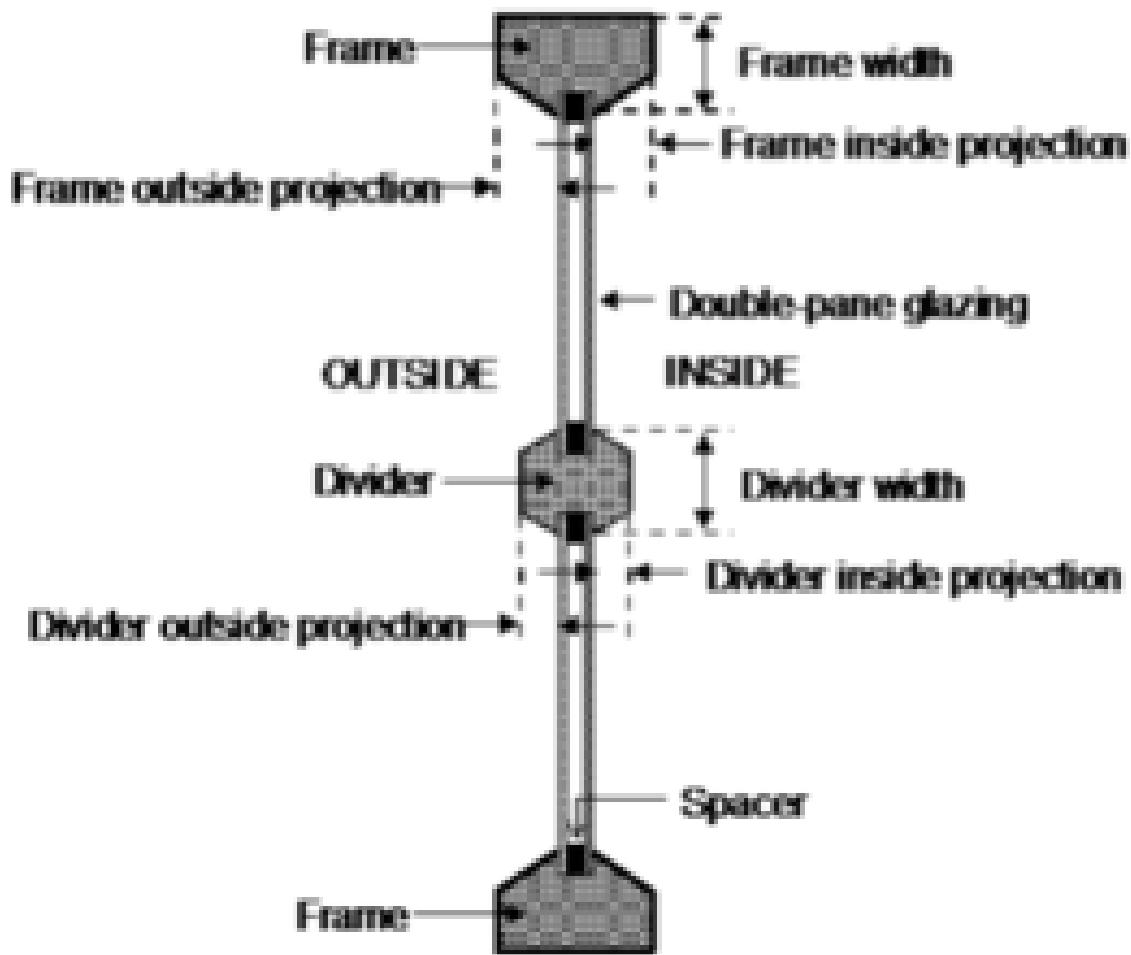

Figure 1.38: Illustration showing frame and divider dimensioning.

### 1.10.62.1.5 Field: Frame Conductance

The effective thermal conductance of the frame measured from inside to outside frame surface (no air films) and taking 2-D conduction effects into account. Obtained from the WINDOW program or other 2-D calculation.

#### 1.10.62.1.6 Field: Ratio of Frame-Edge Glass Conductance to Center-Of-Glass Conductance

The glass conductance near the frame (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the frame and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program the user-selected glazing construction and frame characteristics.

#### 1.10.62.1.7 Field: Frame Solar Absorptance

The solar absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

#### 1.10.62.1.8 Field: Frame Visible Absorptance

The visible absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

#### 1.10.62.1.9 Field: Frame Thermal Hemispherical Emissivity

The thermal emissivity of the frame, assumed the same on the inside and outside.

##### *Divider Fields*

#### 1.10.62.1.10 Field: Divider Type

The type of divider (see figure below). Divider Type = Suspended is applicable only to multi-pane glazing. It means that the divider is suspended between the panes. (If there are more than two glass layers, the divider is assumed to be placed between the two outermost layers.)

Divider Type = DividedLite means that the divider elements project out from the outside and inside surfaces of the glazing and divide the glazing into individual lites. For multi-pane glazing, this type of divider also has between-glass elements that separate the panes.

#### 1.10.62.1.11 Field: Divider Width

The width of the divider elements when projected onto the plane of the window. It is assumed that the horizontal and vertical divider elements have the same width. If not, an average divider width should be entered such that the projected divider area calculated using the average value equals the sum of the areas of the divider elements.

#### 1.10.62.1.12 Field: Number of Horizontal Dividers

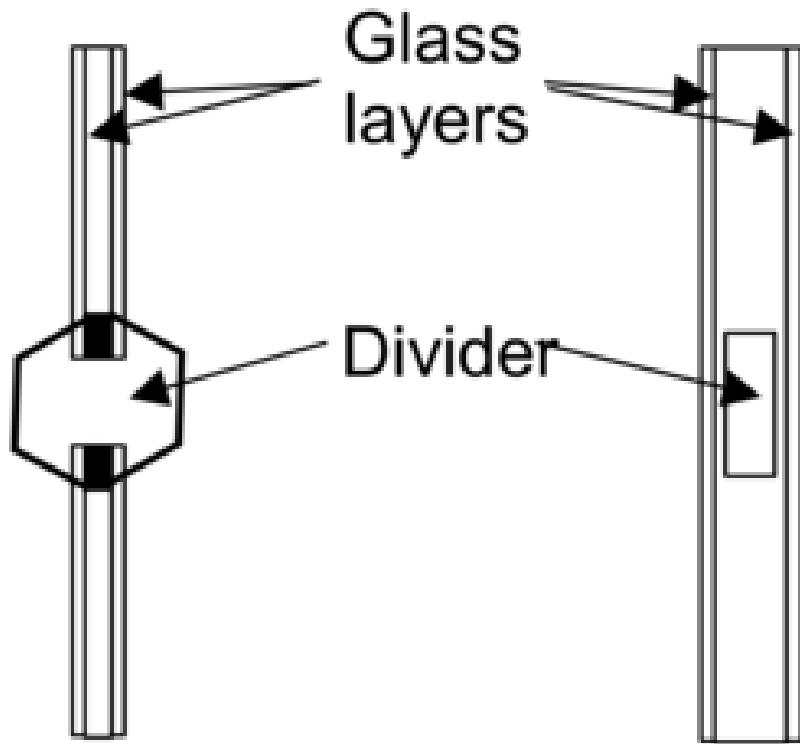

The number of divider elements parallel to the top and bottom of the window.

#### 1.10.62.1.13 Field: Number of Vertical Dividers

The number of divider elements parallel to the sides of the window.

#### 1.10.62.1.14 Field: Divider Outside Projection

The amount by which the divider projects out from the outside surface of the window glazing. For Divider Type = Suspended, Divider Projection = 0.0. Used to calculate shadowing of divider onto glass, solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

**Divider Type =**  
**DividedLite**

**Divider Type =**  
**Suspended**

Figure 1.39: Illustration showing divider types.

### **1.10.62.1.15 Field: Divider Inside Projection**

The amount by which the divider projects inward from the inside surface of the window glazing. If the inner surface of the divider is flush with the glazing, Divider Inside Projection = 0.0. Used to calculate solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

### **1.10.62.1.16 Field: Divider Conductance**

The effective thermal conductance of the divider measured from inside to outside divider surface (no air films) and taking 2-D conduction effects into account. Obtained from the WINDOW program or other 2-D calculation.

### **1.10.62.1.17 Field: Ratio of Divider-Edge Glass Conductance to Center-Of-Glass Conductance**

The glass conductance near the divider (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the divider and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program for the user-selected glazing construction and divider characteristics.

### **1.10.62.1.18 Field: Divider Solar Absorptance**

The solar absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

### **1.10.62.1.19 Field: Divider Visible Absorptance**

The visible absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

### **1.10.62.1.20 Field: Divider Thermal Hemispherical Emissivity**

The thermal emissivity of the divider, assumed the same on the inside and outside.

#### ***Reveal Surface Fields***

The following fields specify the properties of the window reveal surfaces (reveals occur when the window is not in the same plane as the base surface). From this information and from the geometry of the window and the sun position, the program calculates beam solar radiation absorbed and reflected by the top, bottom, right and left sides of outside and inside window reveal surfaces. In doing this calculation, the shadowing on a reveal surface by other reveal surfaces is determined using the orientation of the reveal surfaces and the sun position.

It is assumed that:

- The window is an exterior window.
- The reveal surfaces are perpendicular to the window plane.
- If an exterior shade, screen or blind is in place it shades exterior and interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- If an interior shade or blind is in place it shades the interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- The possible shadowing on inside reveal surfaces by a window divider is ignored.

- The outside reveal surfaces (top, bottom, left, right) have the same solar absorptance and depth. This depth is not input here but is automatically determined by the program—from window and wall vertices—as the distance between the plane of the outside face of the glazing and plane of the outside face of the parent wall.
- The inside reveal surfaces are divided into two categories: (1) the bottom reveal surface, called here the “inside sill;” and (2) the other reveal surfaces (left, right and top).
- The left, right and top inside reveal surfaces have the same depth and solar absorptance. The inside sill is allowed to have depth and solar absorptance values that are different from the corresponding values for the other inside reveal surfaces.
- The inside sill depth is required to be greater than or equal to the depth of the other inside reveal surfaces. If the inside sill depth is greater than zero the depth of the other inside reveal surfaces is required to be greater than zero.
- The reflection of beam solar radiation from all reveal surfaces is assumed to be isotropic diffuse; there is no specular component.
- Half of the beam solar reflected from outside reveal surfaces goes towards the window; the other half goes back to the exterior environment (i.e., reflection of this outward-going component from other outside reveal surfaces is not considered).
- The half that goes towards the window is added to the other solar radiation incident on the window. Correspondingly, half of the beam solar reflected from inside reveal surfaces goes towards the window, with the other half going into the zone. The portion going towards the window that is not reflected is absorbed in the glazing or is transmitted back out into the exterior environment.
- The beam solar that is absorbed by outside reveal surfaces is added to the solar absorbed by the outside surface of the window’s parent wall; similarly, the beam solar absorbed by the inside reveal surfaces is added to the solar absorbed by the inside surface of the parent wall.

The net effect of beam solar reflected from outside reveal surfaces is to increase the heat gain to the zone, whereas the effect of beam solar reflected from inside reveal surfaces is to decrease the heat gain to the zone since part of this reflected solar is transmitted back out the window.

If the window has a frame, the absorption of reflected beam solar by the inside and outside surfaces of the frame is considered. The shadowing of the frame onto interior reveal surfaces is also considered.

#### **1.10.62.1.21 Field: Outside Reveal Solar Absorptance**

The solar absorptance of outside reveal surfaces.

#### **1.10.62.1.22 Field: Inside Sill Depth**

The depth of the inside sill, measured from the inside surface of the glazing to the edge of the sill (see Figure 1.40).

#### **1.10.62.1.23 Field: Inside Sill Solar Absorptance**

The solar absorptance of the inside sill.

##### ***Field: Inside Reveal Depth***

The depth of the inside reveal surfaces other than the sill, measured from the inside surface of the glazing to the edge of the reveal surface (see Figure 1.40).

#### 1.10.62.1.24 Field: Inside Reveal Solar Absorptance

The solar absorptance of the inside reveal surfaces other than the sill.

#### 1.10.62.1.25 Field: NFRC Product Type for Assembly Calculations

The selection made for this field corresponds to NFRC 100 “Procedure for Determining Fenestration Product U-factors” product types which are used when computing the overall u-factor, SHGC, and visual transmittance. The default is CurtainWall. The options are: CasementDouble, CasementSingle, DualAction, Fixed, Garage, Greenhouse, HingedEscape, HorizontalSlider, Jal, Pivoted, Projecting, DoorSidelite, Skylight, SlidingPatioDoor, CurtainWall, SpandrelPanel, SideHingedDoor, DoorTransom, TropicalAwning, TubularDaylightingDevice, and VerticalSlider. The sizes used in the calculation of the overall u-factor, overall SHGC, and overall VT are based on NFRC 100 Table 4-3 (see Figure 1.41 ).

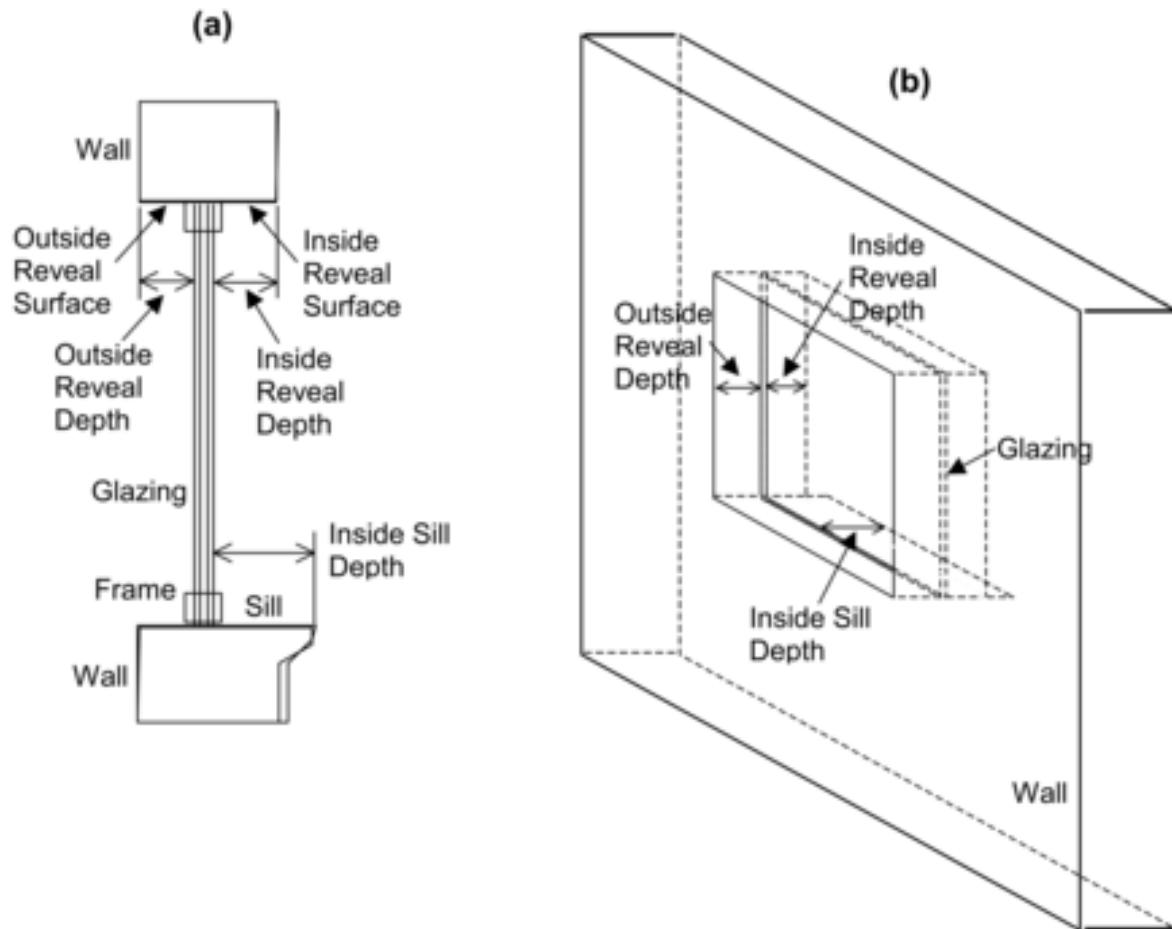

Figure 1.40: (a) Vertical section through a window (with frame) showing outside and inside reveal surfaces and inside sill. (b) Perspective view looking from the outside of a window (without frame) showing reveal surfaces. Note that “Outside Reveal Depth” is not a user input; it is calculated by the program from the window and wall vertices.

### 1.10.63 WindowProperty:AirflowControl

This object is used to specify the control mechanism for windows in which forced air flows in the gap between adjacent layers of glass. Such windows are called “airflow windows.” They are also known as “heat-extract windows” or “climate windows.”

A common application is to reduce the zone load by exhausting indoor air through the window. In the cooling season this picks up and expels some of the solar heat absorbed by the window glass (and by the between-glass shade or blind, if present). In the heating season this warms the window, reducing the heat loss from the window. A side benefit is increased thermal comfort. This is because the inside surface of the window will generally be cooler in summer and warmer in winter.

The surface output variable “Surface Window Gap Convective Heat Transfer Rate” gives the heat picked up (or lost) by the gap airflow.

#### 1.10.63.1 Inputs

##### 1.10.63.1.1 Field: Name

Name of the window that this WindowProperty:AirflowControl refers to. It must be a window with two or three glass layers, i.e., double- or triple-glazing. For triple-glazing the airflow is assumed to be between the two inner glass layers.

An error will result if the gas in the airflow gap is other than air. If an airflow window has a between-glass shade or blind, the gas in the gap on either side of the shade or blind must be air.

##### 1.10.63.1.2 Field: Airflow Source

The source of the gap airflow. The choices are:

*IndoorAir*: Indoor air from the window’s zone is passed through the window.

*OutdoorAir*: Outdoor air is passed through the window.

##### 1.10.63.1.3 Field: Airflow Destination

This is where the gap air goes after passing through the window. The choices are:

*IndoorAir*: The gap air goes to the indoor air of the window’s zone.

*OutdoorAir*: The gap air goes to the outside air.

*ReturnAir*. The gap air goes to the return air for the window's zone. This choice is allowed only if Airflow Source = InsideAir. If the return air flow is zero, the gap air goes to the indoor air of the window's zone. If the sum of the gap airflow for all of the windows in a zone with Airflow Destination = ReturnAir exceeds the return airflow, then the difference between this sum and the return airflow goes to the indoor air. The name of the Return Air Node may be specified below.

Figure 1.42 shows the allowed combinations of Airflow Source and Airflow Destination. The allowed combinations of Airflow Source and Airflow Destination are:

- IndoorAir -> OutdoorAir
- IndoorAir -> IndoorAir
- IndoorAir -> ReturnAir
- OutdoorAir -> IndoorAir
- OutdoorAir -> OutdoorAir

#### 1.10.63.1.4 Field: Maximum Flow Rate

The maximum value of the airflow, in  $\text{m}^3/\text{s}$  per m of glazing width. The value is typically 0.006 to 0.009  $\text{m}^3/\text{s-m}$  (4 to 6 cfm/ft).

The airflow can be modulated by specifying Airflow Has Multiplier Schedule = Yes and giving the name of the Airflow Multiplier Schedule (see below).

The fan energy used to move the air through the gap is generally very small and so is ignored.

#### 1.10.63.1.5 Field: Airflow Control Type

Specifies how the airflow is controlled. The choices are:

*AlwaysOnAtMaximumFlow*. The airflow is always equal to Maximum Airflow.

*AlwaysOff*. The airflow is always zero.

*ScheduledOnly*. The airflow in a particular timestep equals Maximum Airflow times the value of the Airflow Multiplier Schedule for that timestep.

#### 1.10.63.1.6 Field: Airflow Is Scheduled

Specifies if the airflow is scheduled. The choices are:

*Yes*. The airflow is scheduled.

*No*. The airflow is not scheduled.

If Yes, Airflow Multiplier Schedule Name is required.

#### 1.10.63.1.7 Field: Airflow Multiplier Schedule Name

The name of a schedule with values between 0.0 and 1.0. The timestep value of the airflow is Maximum Airflow times the schedule value. Required if Airflow Is Scheduled = Yes. Unused if Airflow Is Scheduled = No. This schedule should have a ScheduleType with Numeric Type = Continuous and Range = 0.0 : 1.0.

#### 1.10.63.1.8 Field: Airflow Return Air Node Name

The name of the return air node for this airflow window if the Airflow Destination is ReturnAir. If left blank, this defaults to the first return air node for the zone containing the window surface.

An IDF example: window with a constant airflow from inside to outside at 0.008  $\text{m}^3/\text{s-m}$ .

```

No,	<i>!- Airflow Is Scheduled</i>
;	<i>!- Airflow Multiplier Schedule Name</i>
,	<i>!- Airflow Return Air Node Name</i>

---

### 1.10.64 WindowProperty:StormWindow

This object allows you to assign a movable exterior glass layer (“storm window” or “storm glass”) that is usually applied to a window in the winter to reduce heat loss and removed in the summer. A WindowProperty:StormWindow object is required for each window that has an associated storm window. It is assumed that:

- When the storm glass is in place it is the outermost layer of the window, it covers only the glazed part of the window and not the frame, and it forms a tight seal. See Figure 1.43.
- When the storm glass is not in place it is completely removed and has no effect on window heat transfer.
- The gap between the storm glass and rest of the glazing is filled with air.

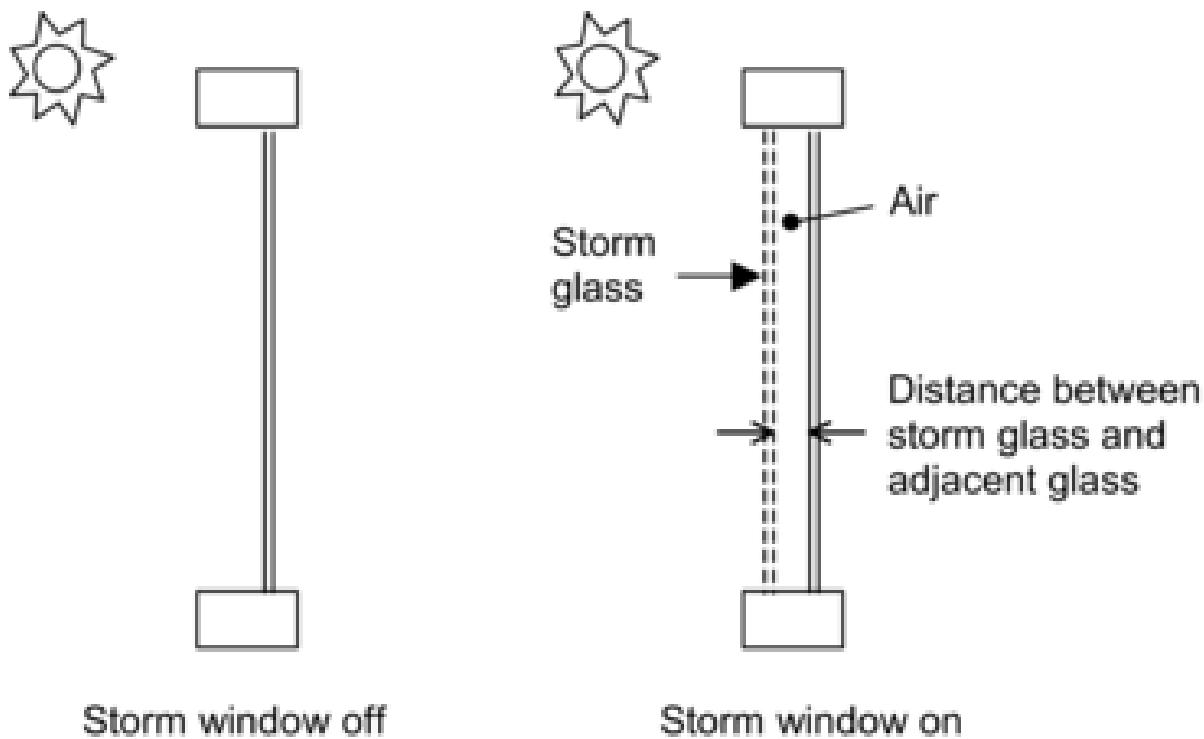

Figure 1.43: Section through a single-glazed window without (left) and with (right) a storm glass layer. Not to scale.

With the addition of a storm window, single glazing effectively becomes double glazing, double glazing becomes triple glazing, etc.

The presence of a storm window is indicated by the output variable “Surface Storm Window On Off Status” (see “Window Output Variables”). This flag is **0** if the storm window is off, **1** if it is on, and **-1** if the window does not have an associated storm window.

The program automatically creates a window construction (ref: Construction) that consists of the storm window glass layer and its adjacent air layer added to the original (unshaded, or “bare”) window construction. In the eplusout.eio file this construction is called BARECONSTRUCTIONWITHSTORMWIN: $n$ , where  $n$  is the number of the associated StormWin object. If the window has a shaded construction, the program creates a construction called SHADEDCONSTRUCTIONWITHSTORMWIN: $n$  that consists of the storm window glass layer and its adjacent air layer added to the original shaded window construction.

The program also creates a **WindowMaterial:Gas** layer corresponding to the air layer adjacent to the storm glass. In the eplusout.eio file this layer is called AIR:STORMWIN: $k$ MM, where  $k$  is the thickness of the air layer expressed as an integer number of millimeters.

### 1.10.64.1 Inputs

#### 1.10.64.1.1 Field: Window Name

This is the name of a window (or glass door) to which the storm glass is applied. Not all windows can accept **WindowProperty:StormWindow**. The rules are:

- The window must be an exterior window. **WindowProperty:StormWindow** is not applicable to interior (interzone) windows.
- The window construction (without the storm glass layer) can have up to three glass layers.
- If the window has an associated shaded construction (ref: **WindowShadingControl**), that construction can have an interior shade or blind and up to three glass layers, or a between-glass shade or blind and two glass layers. The shaded construction cannot have an exterior shade or blind, cannot have a between-glass shade or blind and three glass layers, and cannot be switchable glazing.
- The window cannot be an airflow window, i.e., a window that has an associated **WindowProperty:AirflowControl**.

#### 1.10.64.1.2 Field: Storm Glass Layer Name

This is the name of a window glass material. Storm windows are assumed to consist of a single layer of glass. A storm window frame, if present, is ignored.

#### 1.10.64.1.3 Field: Distance Between Storm Glass Layer and Adjacent Glass

The separation between the storm glass and the rest of the window (Figure 1.43). It is measured from the inside of the storm glass layer to the outside of the adjacent glass layer.

#### 1.10.64.1.4 Field: Month that Storm Glass Layer Is Put On

The number of the month (January = 1, February = 2, etc.) during which the storm window is put in place.

#### 1.10.64.1.5 Field: Day of Month that Storm Glass Layer Is Put On

The day of the month that the storm window is put in place. It is assumed that the storm window is put in place at the beginning of this day, i.e., during the first simulation timestep of the day, and remains in place until that month and day given by the following two fields.

#### 1.10.64.1.6 Field: Month that Storm Glass Layer Is Taken Off

The number of the month (January = 1, February = 2, etc.) during which the storm window is removed.

#### 1.10.64.1.7 Field: Day of Month that Storm Glass Layer Is Taken Off

The day of the month that the storm window is removed. It is assumed that the storm window is removed at the beginning of this day, i.e., during the first simulation timestep of the day, and stays off until the month and day given by Month that Storm Glass Layer Is Put On, Day of Month that Storm Glass Layer Is Put On.

In the northern hemisphere, the month the storm window is put on is generally greater than the month it is taken off (for example put on in month 10, when it starts to get cold, and taken off in month 5, when it starts to warm up). In the southern hemisphere this is reversed: month on is less than month off.

An IDF example of WindowProperty:StormWindow. The storm window is put in place on October 15 and removed on May 1.

```
WindowProperty:StormWindow,

  1;     !- Day of Month that Storm Window Is Taken Off
```

#### 1.10.65 Importing Windows from WINDOW program

WINDOW v6.3 and later is capable of writing IDF excerpts for Window data. This is the preferred method as no external file is necessary. See the Tips document for details on obtaining the IDF excerpt.

The WINDOW program calculates the U-value, Solar Heat Gain Coefficient, solar transmission/absorption characteristics, visible transmission characteristics and other properties of a window under standard indoor and outdoor conditions. WINDOW treats the whole window system—glazing, frame and divider. A sub-program of WINDOW called THERM uses a 2-D finite element calculation to determine the effective conductance of frame, divider and edge-of-glass elements. Another sub-program, OPTICS, determines the solar-optical properties of glazing, including laminates and coated glass.

WINDOW can write a data file containing a description of the window that was analyzed. An example of this file (which is no longer the preferred method) is shown in the Tips document under WINDOW generated files. is shown below. This file, which can be named by the user, can be read by EnergyPlus. For more complete description and examples, see the object description – [Construction:WindowDataFile](#).

In this way, the same window that was created in WINDOW can be imported into EnergyPlus for annual energy analysis without having to re-input the window data. To obtain WINDOW, THERM, or OPTICS go to <http://windows.lbl.gov> and choose the software link. A major advantage of using WINDOW to create window input for EnergyPlus is that you will have direct access to WINDOW's expanding database of over 1000 different glass types; and you will be able to browse through this database according to different criteria (color, transmittance, solar heat gain coefficient, etc.) to help you select the best glass type for your application.

Although WINDOW writes only one window entry on the WINDOW data file, EnergyPlus users can combine two or more of these files to end up with a single data file with multiple window entries of different types. In this way a library of windows from WINDOW can be built up if so desired. If you combine files like this you should be sure not to leave out or change any of lines from the original files.

There are four methods for inputting window constructions in EnergyPlus:

1. input full spectral data for each layer in the IDF,

2. input spectral average data for each layer in the IDF,
3. items 1 and 2 can be accomplished by reporting the IDF excerpt method from WINDOW
4. import WINDOW report containing layer-by-layer calculated values and overall glazing system angular values.

**Note:** When using method 4, the overall glazing system angular dependent properties, including **Tsol**, **Abs**, **Rfsol**, **Rbsol**, **Tvis**, **Rfvis**, and **Rbvis**, are not used by EnergyPlus. Therefore, methods 1 and 2 and preferably 3 are recommended.

- The SHGC calculations in EnergyPlus for window layers input using full spectral data use a spectral weighting data set (derived from Optics5 data file ISO-9845GlobalNorm.std) that is different from the WINDOW default spectral weighting data set (W5\_NFRC\_2003.std). This difference accounts for most of the variation in SHGC values reported by EnergyPlus and WINDOW for full spectral data window layer input. This variation is more pronounced for window constructions of three glass layers or more.
- Users intending to select a window construction based on SHGC value for energy code compliance should base their selection on the value reported by WINDOW since this is the officially recognized value.

In EnergyPlus, the Window data file is searched for each “Construction:WindowDataFile” object in the EnergyPlus input. This object has a very simple form:

```
Construction:WindowDataFile,
  ConstructionName,
  FileName; ! Default is Window5DataFile.dat in the ``run'' folder.
```

If there is a window called ConstructionName on the Window data file, the data for that window is read from the file and the following EnergyPlus objects and their names are created. The “W5” prefixed to these names indicates that the object originated in the Window data file.

### 1.10.66 Using LBNLs Windows Calculation Engine

This is new windows simulation engine that will be used in both EnergyPlus and Berkeley Lab WINDOW. The intent is for this engine to replace all other window calculation modules in EnergyPlus. For the time being, other modules will still be available. To use the new Window Calculation Engine, insert the following into IDF:

```
WindowsCalculationEngine,
ExternalWindowsModel;
```

---

### 1.10.67 Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

```
Zone,Sum,Zone Total Internal Radiant Heating Energy [J]
Zone,Sum,Zone Total Internal Visible Radiation Heating Energy [J]
Zone,Sum,Zone Total Internal Convective Heating Energy [J]
Zone,Sum,Zone Total Internal Latent Gain Energy [J]
Zone,Sum,Zone Total Internal Total Heating Energy [J]
Zone,Average,Zone Mean Air Temperature [C]
HVAC,Average,Zone Air Temperature [C]
```

```

Zone,Average,Zone Mean Radiant Temperature [C]
Zone,Average,Zone Operative Temperature [C]
Zone,Average,Zone Heat Index [C]
Zone,Average,Zone Humidity Index [C]
HVAC,Sum,Zone Air System Sensible Heating Energy [J]
HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
HVAC,Average,Zone Air System Sensible Heating Rate [W]
HVAC,Average,Zone Air System Sensible Cooling Rate [W]
HVAC,Average,Zone Air Humidity Ratio[kgWater/kgDryAir]
HVAC,Average,Zone Air Relative Humidity[%]

```

Two of these are of particular interest:

```

Zone,Average,Zone Mean Air Temperature [C]
HVAC,Average,Zone Air Temperature [C]

```

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. “Zone Mean Air Temperature” is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas “Zone Air Temperature” can be reported at the HVAC timestep (which can vary).

#### **1.10.67.1 Zone Mean Air Temperature [C]**

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a “well stirred” model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

#### **1.10.67.2 Zone Air Temperature [C]**

This is very similar to the mean air temperature in the last field. The “well stirred” model for the zone is the basis, but this temperature is also available at the “detailed” system timestep.

#### **1.10.67.3 Zone Mean Radiant Temperature [C]**

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is really the measure of the combined effects of temperatures of surfaces within that space. The larger the surface area and the closer one is to it, the more effect the surface temperature of that surface has on each other. The MRT is the measure of all these surface areas and temperatures.

#### **1.10.67.4 Zone Operative Temperature [C]**

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT),  $OT = 0.5*MAT + 0.5*MRT$ . This output variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

#### **1.10.67.5 Zone Heat Index [C]**

Zone heat index (HI) is an index that combines air temperature and relative humidity in shaded areas, to posit a human-perceived equivalent temperature, as how hot it would feel if the humidity were some other value in the shade. The HI measures the temperature feels like to the human body when relative humidity is combined with the air temperature. Zone Heat Index is only reported when ThermalResilienceSummary is declared in Output:Table:SummaryReports.

#### 1.10.67.6 Zone Humdity Index [C]

The Humdity Index (humidex) is an index number used by Canadian meteorologists to describe how hot the weather feels to the average person, by combining the effect of heat and humidity. The humidex is a nominally dimensionless quantity (though generally recognized by the public as equivalent to the degree Celsius) based on the dew-point temperature. Zone Humdity Index is only reported when ThermalResilienceSummary is declared in Output:Table:SummaryReports.

#### 1.10.67.7 Zone Air System Sensible Heating Energy [J]

This field represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone Air System Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature. This does not always indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

Note that these variables are calculated at the system timestep. When reported at the “detailed” reporting frequency, these variable will never show heating and cooling both in the same system timestep. If reported at a frequency less than “Detailed” (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

#### 1.10.67.8 Zone Air System Sensible Cooling Energy [J]

This field represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### 1.10.67.9 Zone Air System Sensible Heating Rate [W]

This field represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers. The Zone Air System Sensible Heating Rate may not agree exactly with the equipment-level delivered energy transfer rate when the zone temperature is changing significantly over a timestep (e.g. during thermostat setback and setup), but the energy will balance out over time.

#### 1.10.67.10 Zone Air System Sensible Cooling Rate [W]

This field represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers. The Zone Air System Sensible Cooling Rate may not agree exactly with the equipment-level delivered energy transfer rate when the zone temperature is changing significantly over a timestep (e.g. during thermostat setback and setup), but the energy will balance out over time.

#### 1.10.67.11 Zone Air Humidity Ratio[kgWater/kgDryAir]

This field represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

#### 1.10.67.12 Zone Air Relative Humidity[%]

This field represents the air relative humidity ratio after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

#### 1.10.67.13 Zone Total Internal Radiant Heating Energy [J]

This field represents the sum of radiant gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes radiant gain from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### 1.10.67.14 Zone-Total Internal Visible Heat Gain [J]

This field expresses the sum of heat gain in joules that is the calculated short wavelength radiation gain from lights in the zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the zones in the simulation.

#### 1.10.67.15 Zone Total Internal Convective Heating Energy [J]

This field represents the sum of convective gains from specific sources (e.g. equipment) throughout the zone in joules. This includes convective gain from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### 1.10.67.16 Zone Total Internal Latent Gain Energy [J]

This field represents the sum of latent gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes latent gain from **People**, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### 1.10.67.17 Zone Total Internal Total Heating Energy [J]

This field represents the sum of all heat gains throughout the zone in joules. This includes all heat gains from **People**, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

### 1.11 Group – Advanced Surface Concepts

This group of objects describe concepts applied to heat transfer surfaces that are of an advanced nature. Careful consideration must be given before using these.

### 1.11.1 SurfaceProperty:HeatTransferAlgorithm

This object, and three other related objects, can be used to control which surface heat transfer model is used on specific surfaces. The separate object called **HeatBalanceAlgorithm** is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific surfaces. This object allows selectively overriding the global setting in **HeatBalanceAlgorithm** to choose one of the following models for a particular surface:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

#### 1.11.1.1 Inputs

##### 1.11.1.1.1 Field: Surface Name

This is the name of the surface that will be assigned to use the heat transfer algorithm selected in the next field. This should be a name of a surface defined elsewhere.

##### 1.11.1.1.2 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surface named in the previous field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

### 1.11.2 SurfaceProperty:HeatTransferAlgorithm:MultipleSurface

This object can be used to control the surface heat transfer model used for specific types of surfaces. The separate object called **HeatBalanceAlgorithm** is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific types of surfaces. This object allows selectively overriding the global setting in **HeatBalanceAlgorithm** to choose one of the following models for all surfaces of a particular type:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

#### 1.11.2.1 Inputs

##### 1.11.2.1.1 Field: Name

This is a unique, user-defined name for the object.

### 1.11.2.1.2 Field: Surface Type

This field is selects the type of surfaces that are all assigned to use the heat transfer algorithm selected in the next field. This field is used with one of the following allowable keywords:

- AllExteriorSurfaces—all surfaces that have “Outdoors” outside boundary condition
- AllExteriorWalls—all walls that have “Outdoors” outside boundary condition
- AllExteriorRoofs—all roofs that have “Outdoors” outside boundary condition
- AllExteriorFloors—all floors that have “Outdoors” outside boundary condition
- AllGroundContactSurfaces—all surfaces that have “Ground” outside boundary condition
- AllInteriorSurfaces—all surfaces that are internal partition-type surfaces
- AllInteriorWalls—all walls that are internal surfaces
- AllInteriorCeilings—all ceilings that are internal surfaces
- AllInteriorFloors—all floors that are internal surfaces

### 1.11.2.1.3 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surface types in the previous field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

```
SurfaceProperty:HeatTransferAlgorithm:MultipleSurface,
    my exterior wall override,
    AllExteriorWalls,
    ConductionFiniteDifference;
```

## 1.11.3 SurfaceProperty:HeatTransferAlgorithm:SurfaceList

This object can be used to control the surface heat transfer model used for a list of surfaces. The separate object called **HeatBalanceAlgorithm** is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for a list of specific surfaces. This object allows selectively overriding the global setting in **HeatBalanceAlgorithm** to choose one of the following models for listed:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

### 1.11.3.1 Inputs

#### 1.11.3.1.1 Field: Name

This is a unique, user-defined name for the object.

#### 1.11.3.1.2 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surface listed in the remaining fields. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

#### 1.11.3.1.3 Field: Surface Name N

This is the name of the “Nth” surface that will be assigned to use the heat transfer algorithm selected in this object. These should be the names of surfaces defined elsewhere. This object is extensible. Additional surfaces can be added to extend the object.

An example IDF object follows.

```
SurfaceProperty:HeatTransferAlgorithm:SurfaceList,
  my wall construct override,      !- Name
  ConductionFiniteDifference,     !- Algorithm
  Zn001:Wall001,                  !- Surface Name 1
  Zn001:Wall002,                  !- Surface Name 2
  Zn001:Wall003,                  !- Surface Name 3
  Zn001:Wall004;                  !- Surface Name 4
```

## 1.11.4 SurfaceProperty:HeatTransferAlgorithm:Construction

This object can be used to control the surface heat transfer model used for surfaces that have a specific type of construction. The separate object called **HeatBalanceAlgorithm** is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific constructions. This object allows selectively overriding the global setting in **HeatBalanceAlgorithm** to choose one of the following models for all surfaces with particular type of construction:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

### 1.11.4.1 Inputs

#### 1.11.4.1.1 Field: Name

This is a unique, user-defined name for the object.

#### 1.11.4.1.2 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surfaces with the type of construction listed in the next field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

#### 1.11.4.1.3 Field: Construction Name

This field is the name of a **Construction** object defined elsewhere. All the surfaces in the model that are assigned this type of construction will be assigned to use the heat transfer algorithm selected in the previous field.

An example IDF object follows.

```
SurfaceProperty:HeatTransferAlgorithm:Construction,
  my wall construct override,  !- Name
  ConductionFiniteDifference,  !- Algorithm
  R13WALL;                  !- Construction Name
```

### 1.11.5 SurfaceControl:MovableInsulation

Movable insulation can be used/scheduled on any surface regular surface (such as a wall, floor, roof, etc.) but not on a subsurface (such as a window, use **WindowShadingControl** instead). With movable insulation, no reference is made in the surface that is using the insulation – rather the movable insulation statement references the surface to which it is applied.

Exterior and interior movable insulation have undergone some testing and appears to producing expected results. The underlying principle has been implemented in EnergyPlus for both interior and exterior movable insulation with the possibility for exterior movable insulation to be transparent (transparent insulation material or TIM).

TIM exterior layers can be used with the ConductionFiniteDifference (CondFD) solution algorithm. With this addition, TIM layers can be used in conjunction with wall layers that have phase change materials (PCM) included, or any other advanced capability of the CondFD algorithm such as variable conductivity. The input requirements are exactly the same as when used with the CTF algorithm. The Solution Algorithm needs to be changed to CondFD, and as with CTF, the “SurfaceControl:MovableInsulation” object must be completed to specify the insulated surface and the “**WindowMaterial:Glazing**” or “**WindowMaterial:Glazing:EquivalentLayer**” object is needed to provide the TIM layer properties.

Basically, the addition of movable insulation allows the user to schedule an extra amount of insulation on either the inside or outside surface of a wall (or both). The insulation must be a simple, homogenous material layer (linked to a material definition within the input data file). Note that EnergyPlus allows the exterior movable insulation layer to be transparent to short wavelength radiation (solar). In this case, incident solar is split between the plane between the movable insulation and the surface and the plane between the movable insulation and the surrounding air. This calculation is fairly basic and based on the solar transmittance of the insulation layer (material properties). Using transparent layers for exterior movable insulation allows solar energy to penetrate deeper into a construction where it can be stored for later use in the building (similar in concept to a Trombe Wall).

### 1.11.5.1 Field: Insulation Type

This field determines whether the movable insulation is applied to the inside or the outside of the surface by entering either “Inside” or “Outside”, respectively.

### 1.11.5.2 Field: Surface Name

This field refers the movable insulation back to a particular surface (ref: Building Surfaces) via its user assigned name so that EnergyPlus knows where to apply this extra layer of insulation. This will affect either the inside or outside surface heat balance of this surface depending on the value in the insulation type field (see previous field).

### 1.11.5.3 Field: Material Name

This field refers to a material layer (e.g., `Material`, `Material:NoMass`, `WindowMaterial:Glazing`, or `WindowMaterial:Glazing:EquivalentLayer`; transparent layers are only valid for outside movable insulation) via its user assigned name. This provides the program with a full complement of material properties so that the effect of the insulation (R-value and solar transmittance) can be correctly taken into account by EnergyPlus. Note that for non-glazing materials the solar absorptivity of the layer will be used directly in the calculations. For glazing material layers, the solar absorptivity will be calculated by subtracting both the transmissivity and the front side reflectivity from unity for the material.

### 1.11.5.4 Field: Schedule Name

This field is a schedule that theoretically can be any positive real number but was originally intended to be a parameter between 0.0 and 1.0. Its purpose is to act as a fractional modifier on the resistance of the material layer. The actual thermal resistance of the movable insulation is equal to the resistance of the material layer times the current value in the movable insulation schedule. A value of 0.0 simply means that the movable insulation is not present.

An example of this syntax implemented in an input file is:

```
SurfaceControl:MoveableInsulation,
  Exterior,                      ! Insulation Type
  Zone001:Wall1001,               ! Surface Name
  TransparentInsulationMaterial, ! Material Name
  PresentInWinterSchedule;       ! Schedule Name
```

## 1.11.6 SurfaceProperty:OtherSideCoefficients

By referencing the Other Side Coefficients statement in the surface statements (i.e. Outside Boundary Condition), the temperature of the outer plane of a surface (see Figure 1.44) can be directly controlled. Other side coefficients can also be used to control the exterior convective heat transfer coefficient of a surface and the corresponding exterior air temperature. It should be noted that solar effects are not accounted for when other side coefficients are used. In addition, if other side coefficients are specified for a surface, they also hold for subsurfaces of that surface (though subsurfaces can have their own coefficient set).

other side coefficients have the same effect on all types of heat transfer surfaces. In other words, an interior surface with other side coefficients specified and an exterior wall with identical other side coefficients specified are simulated exactly the same. A surface that uses other side coefficients should be thought of as a new or separate type of surface. All heat transfer surfaces are simulated in the same manner through conduction transfer functions. The only difference between the various types of heat transfer surfaces is

the environment on the other side of the surface. For example, the other side environment of an exterior surface is the outdoor environment. For an interior surface, the temperature of the outer plane of the surface is set equal to the temperature of the inner plane of the surface. Similarly, a surface with other side coefficients specified will allow the user to control the other side environment.

Heat transfer through a surface is an extremely important component in the calculation of zone loads. The information to calculate this heat transfer is readily available if the surface is exposed to the outdoor environment or to another zone that is being simulated. Occasionally, a user will want to model the heat transfer through a surface that is adjacent to an area that is not included in the EnergyPlus model. For example, an office area is attached to a warehouse and the user is only interested in simulating the office area. An interior surface with other side coefficients specified could be used to control the environment on the other side of the surface, thereby accounting for the heat transfer through the adjoining surface.

Other Side Coefficients affects the “other side” of a surface as described below. Each coefficient has a special meaning. You may enter a 0 or blank if you are not using a particular coefficient. Note that there are two potential ways to use other side coefficients. Either they are used to set the temperature of the exterior side surface directly (if the combined convective/radiative coefficient below is less than or equal to zero) or to set both the film coefficient (positive value for the combined convective/radiative coefficient below) and the outside air temperature.

### 1.11.6.1 Inputs

#### 1.11.6.1.1 Field: Name

This, of course, is the string referenced in the Surface statement that is using OtherSideCoefficients as the Outside Boundary Condition.

#### 1.11.6.1.2 Field: Combined Convective/Radiative Film Coefficient

This is a trigger value. If the value is greater than zero, then it is taken to be the combined convective/radiative film coefficient. In this case (value > 0), the remaining fields are used first to calculate the outside air temperature for the surface and then to calculate the outside surface temperature based on the outside air temperature and the film coefficient. If this field is less than or equal to zero, then the remaining fields are used to calculate the surface temperature (not the outside air temperature). The units for this field are the same as for a convective heat transfer coefficient: W/(m<sup>2</sup>\*K). This is referred to as “C1” in the reference below.

#### 1.11.6.1.3 Field: Constant Temperature

This field defines a temperature term that is a constant part of the calculation either of the surface or outside air temperature. This parameter is shown as “C2” in the equation below. The units for this parameter are degrees C. If a schedule name is included as the second parameter, the value of this parameter will be overridden by the value from the schedule. The default for this field is 0.0.

#### 1.11.6.1.4 Field: Constant Temperature Coefficient

This field defines a constant coefficient that is applied to the constant temperature (see previous field). This parameter is shown as “C3” in the equation below. This parameter is dimensionless. The value of this parameter is usually 1.0 if a schedule is used to set C2. This field is ignored if *Sinusoidal Variation of Constant Temperature Coefficient* = Yes. The default for this field is 1.0.

#### 1.11.6.1.5 Field: External Dry-Bulb Temperature Coefficient

This field defines a constant coefficient that is applied to the outside air dry-bulb temperature. This parameter is shown as “C4” in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### 1.11.6.1.6 Field: Ground Temperature Coefficient

This field defines a constant coefficient that is applied to the ground temperature (ref. Site:GroundTemperature:BuildingSurface). This parameter is shown as “C5” in the equation below. This parameter is dimensionless.

#### 1.11.6.1.7 Field: Wind Speed Coefficient

This field defines a constant coefficient that is applied to the product of the outside air dry-bulb temperature and the wind speed. This parameter is shown as “C6” in the equation below. This parameter has dimensions of inverse velocity or s/m. The default for this field is 0.0.

#### 1.11.6.1.8 Field: Zone Air Temperature Coefficient

This field defines a constant coefficient that is applied to the temperature of the zone to which this surface belongs. This parameter is shown as “C7” in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### 1.11.6.1.9 Field: Constant Temperature Schedule Name

This field is used to supply a schedule name. That schedule will supply the “constant” temperature value C2. Note that the value of the C3 field should normally be 1.0 if a schedule is used for C2. If not blank, this field must be a valid schedule name.

#### 1.11.6.1.10 Field: Sinusoidal Variation of Constant Temperature Coefficient

This field is optional and can be used to define an alternate method of prescribing the coefficient that is applied to the constant temperature (see the fields Constant Temperature and Constant Temperature Coefficient). This parameter is shown as “C2” in the equation below. If this field is omitted, left blank, or set to “No,” then C2 is a constant (defined in the field Constant Temperature Coefficient). However, if this is set to “Yes,” then the value of C2 varies with a unitary sine wave in the following way:

$$C2 = \text{Sin} \left( 2\pi \frac{(\text{time of day})}{(\text{period})} \right) \quad (1.19)$$

The value for “period” is controlled in the following field. The value for “time of day” is based on the zone timestep and is in units of hours. The sine function here uses input as radians. When using this option, the value for C2 will vary between -1.0 and 1.0 and the value put in the field Constant Temperature Coefficient is not used. This option cannot be used at the same time as scheduling a constant temperature with the previous field.

#### 1.11.6.1.11 Field: Period of Sinusoidal Variation

This field is used to define the period of the sine wave when using the Sinusoidal Variation of Constant Temperature Coefficient capability selected in the previous field. This field is the time period of the sine wave in units of hours. The default is 24 hours and provides a diurnal sine wave. The value entered here is “period” in the equation in the previous field.

#### 1.11.6.1.12 Field: Previous Other Side Temperature Coefficient

This field defines a constant coefficient that is applied to the other side temperature computed by this object from the previous zone time step. This parameter is shown as “C8” in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### 1.11.6.1.13 Field: Minimum Other Side Temperature Limit

This field specifies a lower limit for the other side temperature result in degrees C. If blank, there is no lower limit.

#### 1.11.6.1.14 Field: Maximum Other Side Temperature Limit

This field specifies an upper limit for the other side temperature result in degrees C. If blank, there is no upper limit.

The coefficients listed above are used in the following equation:

$$T = C2 * C3 + C4 * Toadb + C5 * Tgrnd + C6 * Wspd * Toadb + C7 * Tzone + C8 * Tpast \quad (1.20)$$

where:

T = Outside Air Temperature when C1 (Combined convective/radiative film Coeff) > 0

T = Exterior Surface Temperature when C1 (Combined convective/radiative film Coeff) <= 0

Tzone = Temperature of the zone being simulated (°C)

Toadb = Dry-bulb temperature of the outdoor air (°C)

Tgrnd = Temperature of the ground (°C) from Site:GroundTemperature:BuildingSurface

Wspd = Outdoor wind speed (m/sec)

Tpast = Other side temperature from previous zone timestep (°C)

## 1.11.6.2 Outputs

`Zone,Average, Surface Other Side Coefficients Exterior Air Drybulb Temperature`

### 1.11.6.2.1 Surface Other Side Coefficients Exterior Air Drybulb Temperature [C]

This is the air temperature applied to the other side of the surface.

## 1.11.7 SurfaceProperty:OtherSideConditionsModel

By referencing the Other Side Conditions Model statement in the surface statements (i.e. Outside Boundary Condition), the boundary conditions for the outer plane of the mass wall can be connected to the appropriate model for various multi-skin components. The types of multi-skin components that use this object include systems that are mounted to the outside surface using standoffs that create a small air gap – see Figure 1.45. This type of modeling allows using the usual heat transfer calculations for the underlying surface with other types of multi-skin component models that are available including: unglazed transpired solar collectors, ventilated photovoltaic panels, and naturally ventilated facades.

The boundary condition values are determined dynamically by the program using internal component models. If you want to define other side surface temperatures or convection conditions, then use `SurfaceProperty:OtherSideCoefficients` instead of this object.

It should be noted that when other side conditions models are used, solar effects are removed from the surface's outside face heat balance but are used in modeling the component adjacent to that surface.

The other side conditions model also includes underground piping system interaction. The `PipingSystem:Underground:Domain` object represents a mass of ground which may include interaction with, for example, basement surfaces. In this case, the ground model will internally use the other side condition model hook to update boundary conditions for those surfaces which use that other side condition model name reference.

The other side conditions model also includes an underwater boundary condition connection. By specifying “ConvectiveUnderwater” as the boundary type, and including any number of “`SurfaceProperty:Underwater`” objects in the input, the user can connect surfaces to water such as for a moving vessel.

## 1.11.7.1 Inputs

### 1.11.7.1.1 Field: Name

This is the string referenced in the Surface statement that is using OtherSideModel as the Exterior Environment.

### 1.11.7.1.2 Field: Type of Modeling

This is a string key selection used to identify the type of model that will be used to determine boundary conditions. The only available choices are "GapConvectionRadiation," "UndergroundPipingSystemSurface," "GroundCoupledSurface," and "ConvectiveUnderwater."

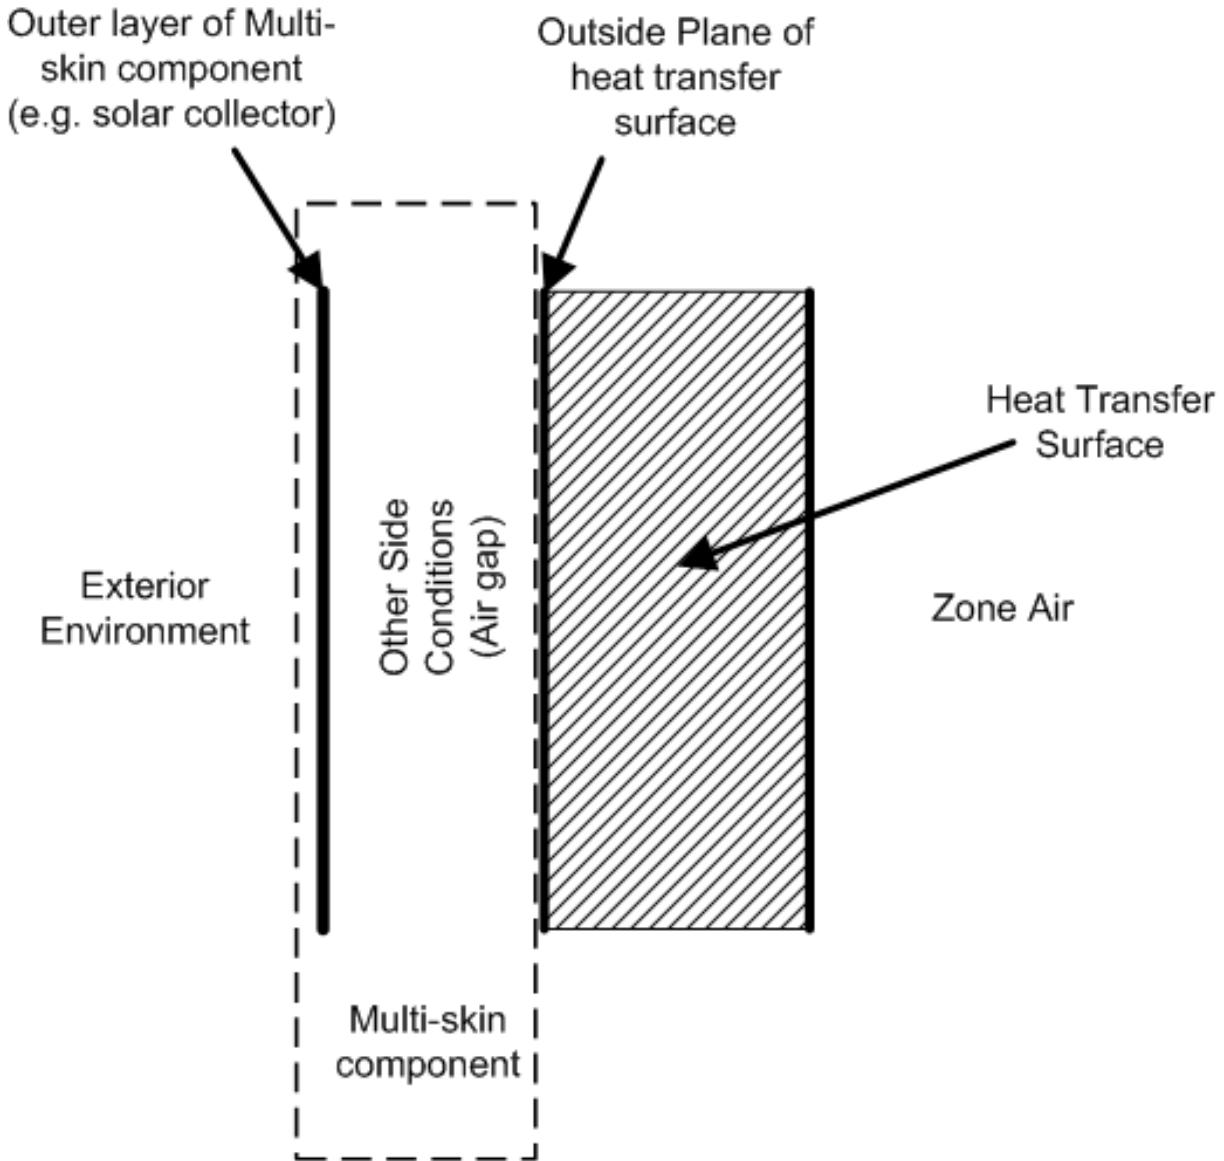

Figure 1.45: Illustration for Other Side Conditions Model

An example specification is:

```
SurfaceProperty:OtherSideConditionsModel,
    UTSC OSCM ZN11,           ! OtherSideConditionsModel Name
    GapConvectionRadiation; ! Type of Modeling used to determine Boundary Conditions
```

### 1.11.7.2 Outputs

- Zone,Average,Surface Other Side Conditions Modeled Convection Air Temperature [C]

- Zone,Average,Surface Other Side Conditions Modeled Convection Heat Transfer Coefficient [W/m<sup>2</sup>-K]
- Zone,Average,Surface Other Side Conditions Modeled Radiation Temperature [C]
- Zone,Average,Surface Other Side Conditions Modeled Radiation Heat Transfer Coefficient [W/m<sup>2</sup>-K]

### **1.11.7.2.1 Surface Other Side Conditions Modeled Convection Air Temperature [C]**

This is the air temperature exposed to the other side of the surface by the model and used in convection heat transfer calculations.

### **1.11.7.2.2 Surface Other Side Conditions Modeled Convection Heat Transfer Coefficient [W/m<sup>2</sup>-K]**

This is the surface convection heat transfer coefficient applied to the other side of the surface by the model.

### **1.11.7.2.3 Surface Other Side Conditions Modeled Radiation Temperature [C]**

This is the effective temperature exposed to the other side of the surface for thermal radiation heat transfer calculations.

### **1.11.7.2.4 Surface Other Side Conditions Modeled Radiation Heat Transfer Coefficient [W/m<sup>2</sup>-K]**

This is the effective (Linearized) radiation heat transfer coefficient applied to the other side of the surface by the model.

## **1.11.8 SurfaceProperty:Underwater**

This object captures the inputs required to model a water-connected boundary condition for a surface. This model is useful for either statically positioned buildings with natural convection to the water boundary condition, or a moving building (vessel).

### **1.11.8.1 Inputs**

#### **1.11.8.1.1 Field: Name**

This is the string referenced in the Surface statement that is using this OtherSideModel as the Exterior Environment.

#### **1.11.8.1.2 Field: Distance from Surface Centroid to Leading Edge of Boundary Layer**

This distance represents the distance from the centroid of this particular surface to leading edge of the boundary layer. For a surface with zero velocity, this field will be irrelevant, because there is no forced boundary layer, and convection will be buoyantly driven. For a moving vessel, this distance should be the nominal distance from the leading edge of the vessel, assuming a nearly flat surface along that path.

#### **1.11.8.1.3 Field: Free Stream Water Temperature Schedule**

This schedule defines the temperature of the free stream water used in the convection calculations.

#### 1.11.8.1.4 Field: Free Stream Water Velocity Schedule

This schedule defines the average velocity of the free stream water used in the convection calculations. This schedule could be the water velocity as it moves past stationary surface, the surface velocity as it moves past stationary water, or an effective velocity as a result of the combination.

An example specification is:

```

```

#### 1.11.9 Foundation:Kiva

Foundation:Kiva objects describe boundary conditions for ground-coupled foundation surfaces. Surfaces with the “Outside Boundary Condition” defined as “Foundation”, may also refer to a Foundation:Kiva object in the “Outside Boundary Condition Object” field (if unspecified, a default Foundation:Kiva object will be created and applied).

Limitations when using Foundation:Kiva objects include:

- Only floors and walls may use Foundation:Kiva objects as Outside Boundary Conditions.
- For a given zone, each floor surface must reference a different Foundation:Kiva object. In other words, multiple foundation floor surfaces may exist in the same thermal zone so long as they reference separate Foundation:Kiva objects. The same Foundation:Kiva object may be referenced by multiple floors so long as they are in different zones.
- Any number of wall surfaces may reference a single Foundation:Kiva object so long as that object is referenced by exactly one floor surface in the same thermal zone.
- Foundation wall surfaces that are not triangular or quadrilateral may not translate well into the two-dimensional finite difference context.

For each floor surface with “Foundation” set as the “Outside Boundary Condition” there must also be a corresponding “[SurfaceProperty:ExposedFoundationPerimeter](#)” object to define how much of the floor perimeter is below exterior walls.

The inputs from Foundation:Kiva objects are translated into Kiva’s foundation heat transfer model. Kiva™ generates a two-dimensional heat transfer calculation to represent heat flow between a zone and the adjacent ground. Foundation:Kiva surfaces do not use the same [HeatBalanceAlgorithm](#) (e.g., Conduction Transfer Functions) as the rest of the model.

Foundation:Kiva objects are used to describe the two-dimensional features that cannot be captured by the typical one-dimensional constructions used in EnergyPlus. Figure 1.46 illustrates Kiva’s two-dimensional context for a basement where the basement slab and wall both refer to “Foundation” as the Outside Boundary Condition, the ceiling of the basement and the exterior wall of the zone above the basement refer to “Surface” (or “Zone”) and “Outdoors”, respectively. Note: Not all of the foundation wall surface needs to be below grade (see the “Wall Height Above Grade” field for this object). Any part

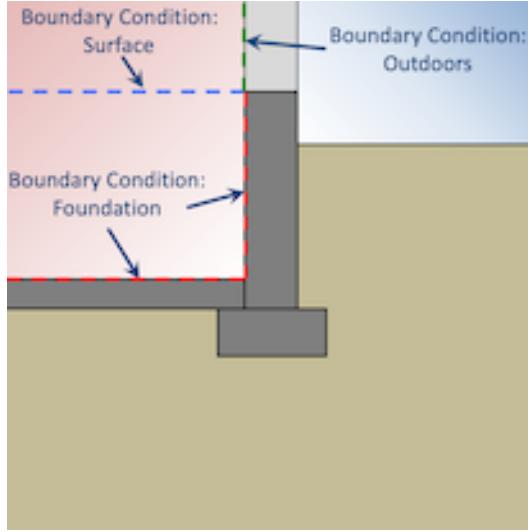

Figure 1.46: Outside Boundary Conditions for surfaces within Kiva’s Two-dimensional context. Only surfaces referencing “Foundation” are simulated in Kiva

of the foundation wall above grade is modeled in Kiva’s two-dimensional heat transfer calculations. The non-foundation surfaces are shown in Figure 1.46 for context, but are not part of the Kiva model.

This context allows for a finer description of the structural and insulation components of a foundation that impact heat transfer (Figure 1.47).

Foundation:Kiva objects define only the aspects of the foundation that are not already defined by the one-dimensional constructions of the respective surfaces. That is, the footing wall and slab constructions and their relative dimensions are inferred from the respective Surface objects (see Figure 1.48).

The depth of the foundation is defined by the height of the wall surfaces that reference the Foundation:Kiva boundary condition object. For slab-on-grade foundations, a depth of zero is implied by having no associated wall surfaces. Figure 1.49 shows a slab-on-grade foundation with whole slab insulation. Notice there are no walls referencing the “Foundation” Outside Boundary Condition. In this case, the under-slab insulation is modeled as part of the slab construction, while the edge/gap insulation is modeled using the interior vertical insulation fields of a Foundation:Kiva object. Note: Since there are no wall surfaces for slab foundations, the footing wall construction is defined within the Foundation:Kiva object (or defaulted to a 0.3m wide cast concrete wall).

A walkout basement (with a variable grade along the sides; see Figure 1.50) is best modeled using discrete quadrilateral surfaces of stepped height for the walls as shown in Figure 1.51.

The width of the floor surface in the two-dimensional context is defined by the area and the exposed perimeter (see [SurfaceProperty:ExposedFoundationPerimeter](#)) of the floor surface object. Details on this calculation can be found in the Engineering Reference document.

Other components of the two-dimensional context are defined by the [Foundation:Kiva:Settings](#) object and applied uniformly for all instances of Foundation:Kiva objects. These components include:

- Far-Field width
- Deep Ground depth (and boundary type)
- Soil and ground surface thermal properties

### 1.11.9.2 Inputs

#### 1.11.9.2.1 Field: Name

The unique identifier of the Foundation:Kiva object. Referenced by a the “Outside Boundary Condition Object” field in a surface object.

#### 1.11.9.2.2 Field: Initial Indoor Air Temperature

Indoor air temperature used for Kiva initialization (prior to warmup period). If left blank, indoor air temperature during initialization will be estimated based on zone setpoints.

#### 1.11.9.2.3 Field: Interior Horizontal Insulation Material Name

A reference to a material object associated with the interior horizontal insulation. If left blank, no interior horizontal insulation will be used. Default: blank.

The following two fields define the placement of this material within Kiva’s two-dimensional context and are illustrated in Figure 1.52.

#### 1.11.9.2.4 Field: Interior Horizontal Insulation Depth

Distance from the bottom of the slab to the top of interior horizontal insulation, in m. Generally, interior horizontal insulation is placed directly below the slab, and therefore, this value will generally be

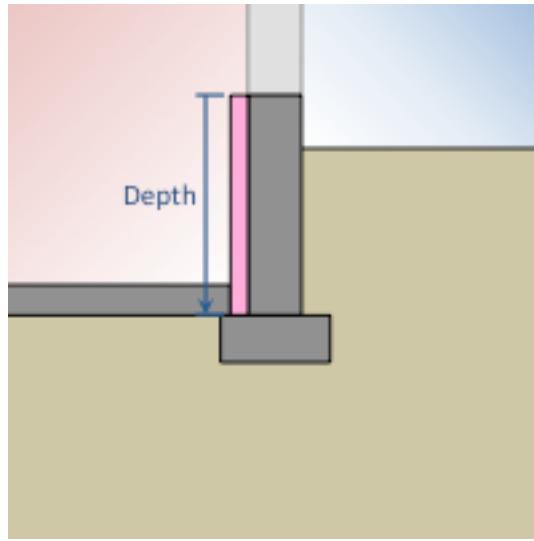

Figure 1.53: Placement of interior vertical insulation

set to zero (as indicated in Figure 1.52). Required if Interior Horizontal Insulation Material Name is defined.

#### 1.11.9.2.5 Field: Interior Horizontal Insulation Width

Extent of insulation as measured from the wall interior to the edge of interior horizontal insulation, in m. Required if Interior Horizontal Insulation Material Name is defined.

#### 1.11.9.2.6 Field: Interior Vertical Insulation Material Name

A reference to a material object associated with the interior vertical insulation. If left blank, no interior vertical insulation will be used. Default: blank.

The following field defines the placement of this material within Kiva's two-dimensional context and are illustrated in Figure 1.53.

#### 1.11.9.2.7 Field: Interior Vertical Insulation Depth

Extent of insulation as measured from the wall top to the bottom edge of the interior vertical insulation, in m. Required if Interior Vertical Insulation Material Name is defined.

#### 1.11.9.2.8 Field: Exterior Horizontal Insulation Material Name

A reference to a material object associated with the exterior horizontal insulation. If left blank, no exterior horizontal insulation will be used. Default: blank.

The following two fields define the placement of this material within Kiva's two-dimensional context and are illustrated in Figure 1.54.

#### 1.11.9.2.9 Field: Exterior Horizontal Insulation Depth

Distance from the exterior grade to the top of exterior horizontal insulation, in m. Required if Exterior Horizontal Insulation Material Name is defined.

#### 1.11.9.2.10 Field: Exterior Horizontal Insulation Width

Extent of insulation as measured from the wall exterior to the edge of exterior horizontal insulation, in m. Required if Exterior Horizontal Insulation Material Name is defined.

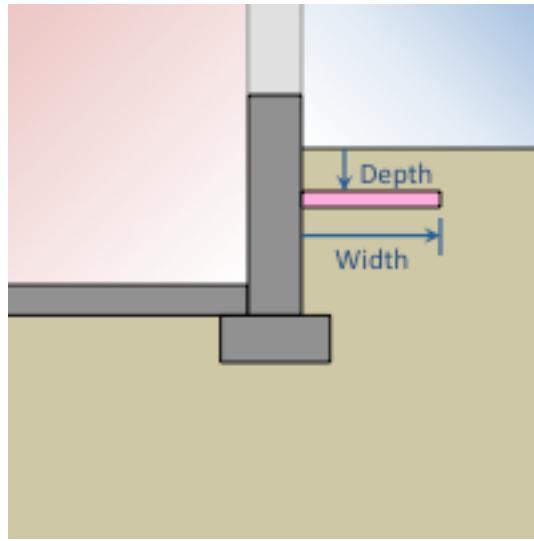

Figure 1.54: Placement of exterior horizontal insulation

#### 1.11.9.2.11 Field: Exterior Vertical Insulation Material Name

A reference to a material object associated with the exterior vertical insulation. If left blank, no exterior vertical insulation will be used. Default: blank

The following field defines the placement of this material within Kiva's two-dimensional context and are illustrated in Figure 1.55.

#### 1.11.9.2.12 Field: Exterior Vertical Insulation Depth

Extent of insulation as measured from the wall top to the bottom edge of the exterior vertical insulation, in m. Required if Exterior Vertical Insulation Material Name is defined.

#### 1.11.9.2.13 Field: Wall Height Above Grade

Distance from the exterior grade to the wall top, in m. Default: 0.2 m

Figures 1.56 and 1.57 illustrate the definition of both the “Wall Height Above Grade” and the following field, “Wall Depth Below Slab”. If the top of foundation wall is flush with the ground then the “Wall Height Above Grade” is zero.

#### 1.11.9.2.14 Field: Wall Depth Below Slab

Distance from the slab bottom to the bottom of the foundation wall, in m. Default: 0.0 m

Extending the wall below the slab provides a coarse approximation of the foundation footing. Alternatively, one may use the fields “Footing Material Name” and “Footing Depth” to explicitly model the footing. Note, that explicit modeling of the footing requires a higher spatial discretization and, therefore, longer computation times.

#### 1.11.9.2.15 Field: Footing Wall Construction Name

Defines the construction of the foundation footing wall for slab foundations where the foundation wall is not exposed to the zone (and has no zone surface to explicitly assign a construction).

By default, this is the same construction as any associated below-grade wall surfaces, or a 0.3 m wide poured concrete wall (conductivity = 1.95 W/m-K, density = 2240 kg/m<sup>3</sup>, specific heat = 900 J/kg-K).

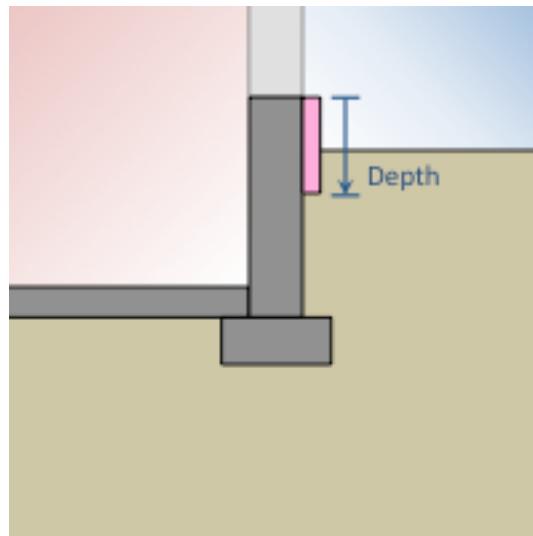

Figure 1.55: Placement of exterior vertical insulation

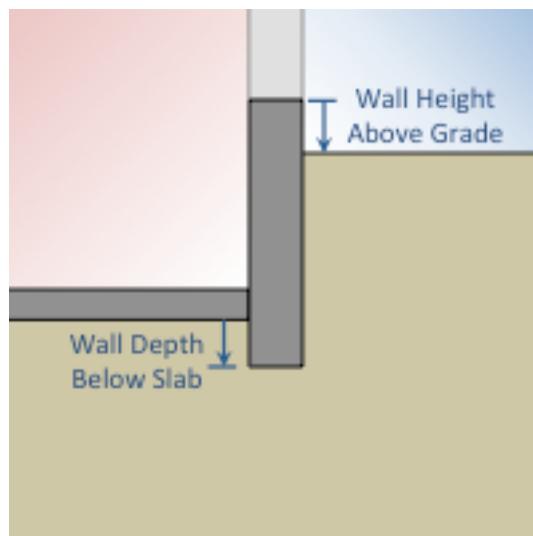

Figure 1.56: Definition of exterior grade and footing wall depth relative to the wall surface (for a basement foundation context)

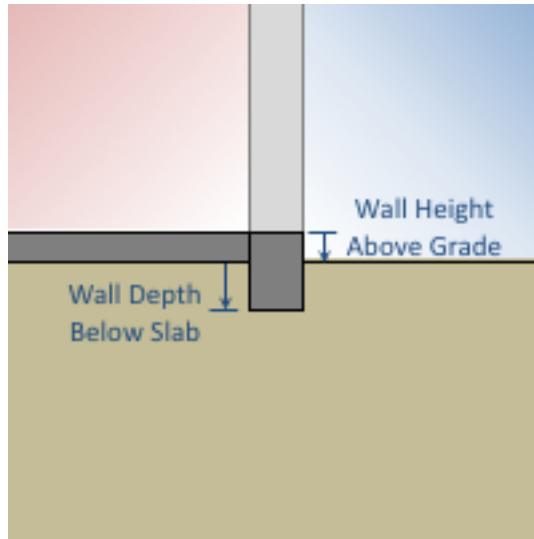

Figure 1.57: Definition of exterior grade and footing wall depth relative to the wall surface (for a slab foundation context)

#### 1.11.9.2.16 Field: Footing Material Name

A reference to a material object associated with the foundation footing (typically some form of concrete). The thickness of this material is used to determine the width of the footing. If left blank, no footing will be used. Default: blank

The following field defines the placement of this material within Kiva's two-dimensional context and are illustrated in Figure 1.58.

#### 1.11.9.2.17 Field: Footing Depth

Top-to-bottom dimension of the footing (not to be confused with its depth in the ground). The width of the footing is defined by the material's thickness. Default: 0.3 m.

#### 1.11.9.2.18 Field: Custom Block <x> Material Name

A reference to a material object associated with a custom block in the two-dimensional foundation context. The thickness of this material determines the width of the block.

Custom blocks can be used to represent solid materials in the two-dimensional context that are not otherwise covered by the fields above. Examples of this might include interior finishings and insulation (Figure 1.59) or backfill soil with different thermal properties (Figure 1.60).

If two or more custom blocks overlap, the final properties are determined by the higher block number (e.g., Custom Block 4 in the input object supersedes properties defined by Custom Block 2). All custom blocks properties are superseded by the elements shown in Figure 1.47.

The following fields defines the placement of this material within Kiva's two-dimensional context and are illustrated in Figure 1.61.

#### 1.11.9.2.19 Field: Custom Block <x> Depth

Top-to-bottom dimension of the block downward. The default is the depth from the wall top to the top of the slab to facilitate interior constructions. Default: Slab depth

#### 1.11.9.2.20 Field: Custom Block <x> X Position

Position outward (+) or inward (-) relative to the foundation wall.

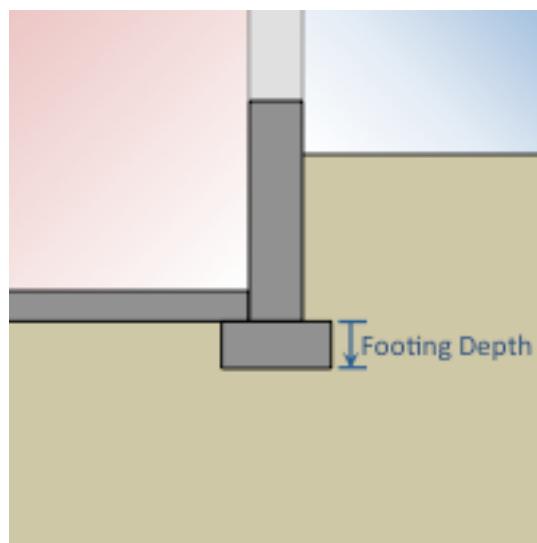

Figure 1.58: Placement of footing

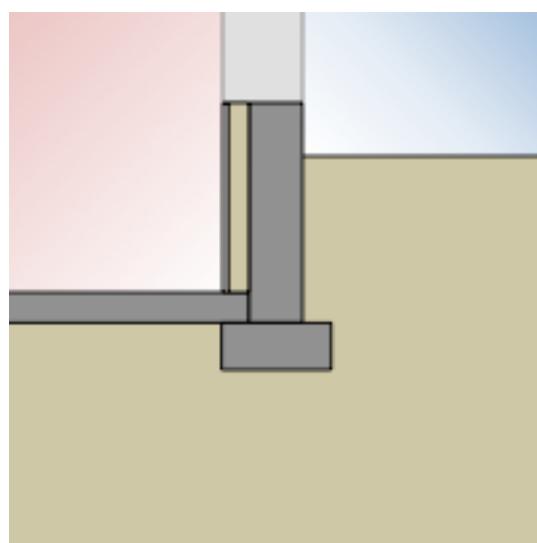

Figure 1.59: Custom blocks representing interior batt insulation and dry wall

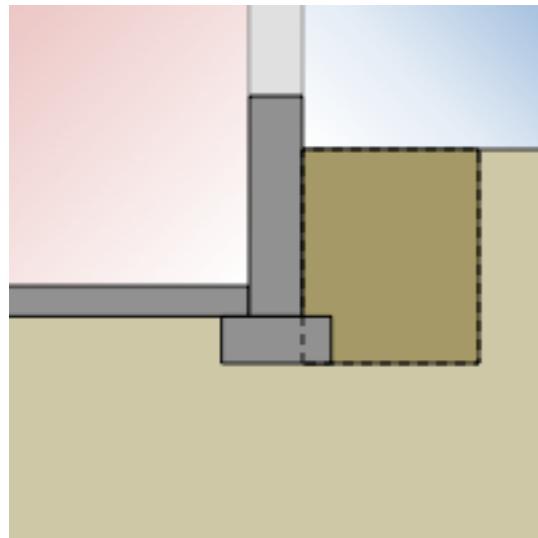

Figure 1.60: Custom block representing exterior backfill

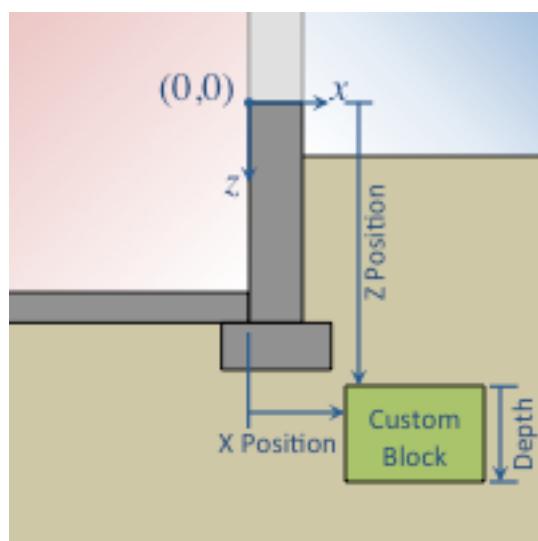

Figure 1.61: Placement of a custom block

**1.11.9.2.21 Field: Custom Block <x> Z Position**

Position downward (+) relative to the foundation wall top. Default: Wall top

**1.11.9.3 Outputs**

Output for surfaces with a Foundation boundary condition type will include all opaque surface output variables except:

- Surface Outside Face variables (since there is no “Outside Face”)
- Surface Heat Storage variables (since this definition depends on an “Outside Face”)
- Surface Internal Source Location Temperature (Kiva doesn’t handle internal sources yet, but this is a possible future enhancement)

**1.11.10 Foundation:Kiva:Settings**

This object defines settings applied across all Kiva foundation calculations. This object is not required. If it is not defined, all defaults will be applied.

**1.11.10.1 Inputs****1.11.10.1.1 Field: Soil Conductivity**

The thermal conductivity of the soil, in W/m-K. Default: 1.73 W/m-K.

**1.11.10.1.2 Field: Soil Density**

The bulk density of the soil, in kg/m3. Default: 1842 kg/m3.

**1.11.10.1.3 Field: Soil Specific Heat**

The specific heat of the soil, in J/kg-K. Default: 419 J/kg-K

**1.11.10.1.4 Field: Ground Solar Absorptivity**

Solar absorptivity of the exterior grade surface. Default: 0.9.

**1.11.10.1.5 Field: Ground Thermal Absorptivity**

Long-wave absorptivity (emissivity) of the exterior grade surface. Default: 0.9.

**1.11.10.1.6 Field: Ground Surface Roughness**

The relief roughness of the exterior ground surface in m. Default: 0.03 m.

Estimates of surface roughnesses in m are shown in Table 1.15.

Table 1.15: Example Surface and Roughness

Example Surface	Roughness [m]
Concrete	0.002
Brick	0.003
Soil	0.005
Gravel	0.012
Grass	0.030

### 1.11.10.1.7 Field: Far-Field Width

The distance from the wall interior to the zero horizontal heat flux (i.e., adiabatic) far-field boundary, in m. This distance represents either the distance halfway between this foundation and a similar foundation of a neighboring building, or a distance adequately far from the foundation such that it is isolated from the effects of the boundary (typically  $\geq 40$  m). Default: 40 m.

### 1.11.10.1.8 Field: Deep-Ground Boundary Condition

Defines the type of boundary condition to apply at the Deep-Ground Depth. Options are:

- ZeroFlux
- GroundWater
- Autoselect

ZeroFlux applies a zero vertical heat flux (i.e. adiabatic) boundary condition. GroundWater applies a constant temperature boundary condition, with a temperature equal to the average outdoor air dry-bulb temperature from the environment(s). Autoselect applies either boundary condition depending on the elevation of the building site (Williams and Williamson, 1989):

$$d_{wt} = 0.1022 \cdot d_{elev}$$

If  $d_{wt} \leq 40$  m., the GroundWater boundary is applied at this depth, otherwise a ZeroFlux boundary is applied at 40 m. If the calculated ground water depth is shallower than any element of a foundation construction, then the GroundWater is applied at 1 m below the lowest element for that foundation.

Default: Autoselect.

### 1.11.10.1.9 Field: Deep-Ground Depth

The distance from the exterior grade to the deep ground boundary, in m. This distance represents either the distance to the ground water level, or a distance adequately far from the foundation such that it is isolated from the effects of the boundary (typically  $\geq 40$  m). Default 40 m, or the distance determined by the “Autoselect” Deep-Ground Boundary Condition. If the Deep-Ground Boundary Condition is set to “Autoselect”, this field should be set to “Autocalculate”. If the Deep-Ground Boundary Condition is not set to “Autoselect”, but this field is set to “Autocalculate” (or allowed to default), an error will be issued.

Default: Autocalculate.

### 1.11.10.1.10 Field: Minimum Cell Dimension

The minimum cell dimension, in m, used in the Kiva discretization. Default: 0.02 m.

### 1.11.10.1.11 Field: Maximum Cell Growth Coefficient

The maximum ratio of growth between neighboring cells in the direction away from the near-field area of interest. Default: 1.50.

### 1.11.10.1.12 Field: Simulation Timestep

This field allows the user to choose whether to calculate foundation loads on the zone timestep or at hourly intervals. Hourly intervals will allow for less overall computation time, but with less accuracy. Choices are “Hourly” and “Timestep”. Default: Hourly

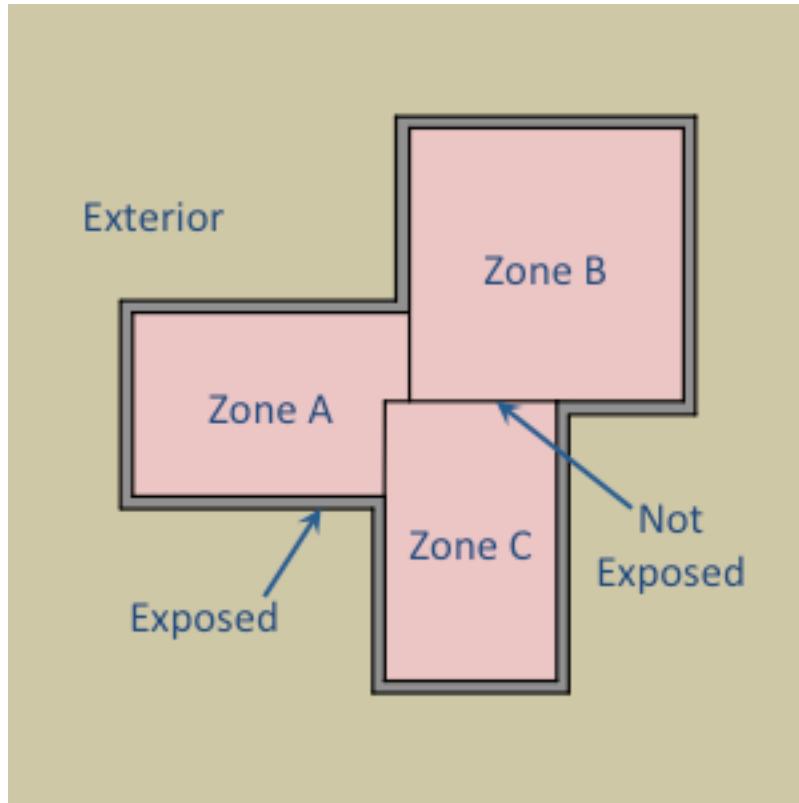

Figure 1.62: Exposed foundation perimeter

### 1.11.11 SurfaceProperty:ExposedFoundationPerimeter

This object (currently only used in conjunction with **Foundation:Kiva** boundary conditions) defines the perimeter of a foundation floor that is exposed to the exterior environment through the floor. The user may either define the total exposed perimeter, the fraction of the total perimeter that is exposed, or individually define which segments of the floor surface perimeter are exposed. This object is required for any floor surface with a **Foundation:Kiva** boundary condition.

Figure 1.62 illustrates how the exposed perimeter is determined from a floor plan of the foundation level.

Some buildings may have neighboring zones with different foundation types. For example, a crawlspace next to a garage with a slab (Figure 1.63). The foundation wall in this case is NOT considered part of either floor's exposed perimeter, and should not reference a Foundation boundary condition. Kiva does not calculate heat flow between two zones through ground. In this case, it is best to approximate interior foundation wall using an Adiabatic Outside Boundary Condition.

#### 1.11.11.1 Inputs

##### 1.11.11.1.1 Field: Surface Name

Name of foundation floor surface object.

##### 1.11.11.1.2 Field: Exposed Perimeter Calculation Method

Required key/choice field that tells which method to use to calculate the exposed foundation perimeter. Choices are:

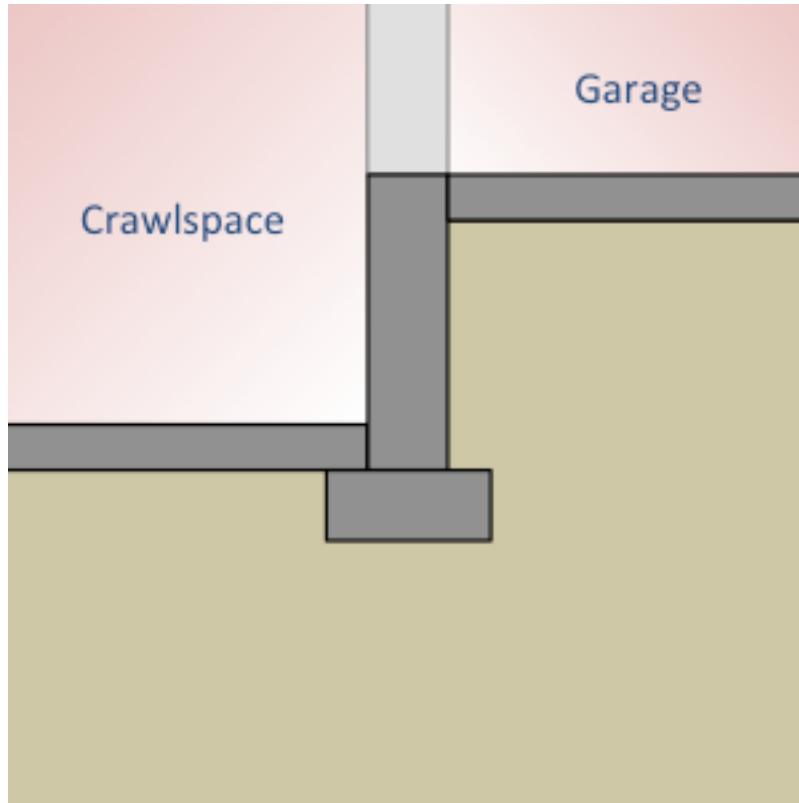

Figure 1.63: Interior foundation wall

- **TotalExposedPerimeter:** Exposed perimeter is defined as an absolute distance in m. (The Total Exposed Perimeter field should be filled.)
- **ExposedPerimeterFraction:** Exposed perimeter is defined as a fraction of the total floor perimeter. (The Exposed Perimeter Fraction field should be filled.) Note: This option works best when you are confident that the floor surface is completely exposed.
- **BySegment:** Each segment of the floor polygon (corresponding to distance between each set of vertices) is defined as exposed (“Yes”) or not exposed (“No”) in an extensible list corresponding to the number of vertices in the floor polygon. Exposed perimeter is defined as the sum of all exposed segment lengths. (The Surface Segment  $< x >$  Exposed fields should be filled.) Note: The number of segments identified in this object must match the number of vertices in the corresponding surface object.

#### 1.11.11.1.3 Field: Total Exposed Perimeter

Total perimeter that is exposed in m.

#### 1.11.11.1.4 Field: Exposed Perimeter Fraction

Fraction of the total perimeter that is exposed. Default 1.0

#### 1.11.11.1.5 Field: Surface Segment $< x >$ Exposed

Surface Segment  $< x >$  is the perimeter between the  $< x >$ th and ( $< x > + 1$ )th vertices.

## 1.11.12 SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections

This object provides options to change the individual convection model equations for dynamic selection when using AdaptiveConvectionAlgorithm. This object is only needed to make changes to the default model selections for any or all of the surface categories. This object is for the inside face, the side of the surface facing a thermal zone.

### 1.11.12.1 Inputs

#### 1.11.12.1.1 Field: Name

A unique name for the object.

#### 1.11.12.1.2 Field: Simple Buoyancy Vertical Wall Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for vertical walls. The key choice options include: FohannoPolidoriVerticalWall, ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, KhalifaEq6NonHeatedWalls FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve

#### 1.11.12.1.3 Field: Simple Buoyancy Vertical Wall User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### 1.11.12.1.4 Field: Simple Buoyancy Stable Horizontal Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

#### 1.11.12.1.5 Field: Simple Buoyancy Stable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### 1.11.12.1.6 Field: Simple Buoyancy Unstable Horizontal Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for passive horizontal surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

#### 1.11.12.1.7 Field: Simple Buoyancy Unstable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### 1.11.12.1.8 Field: Simple Buoyancy Stable Tilted Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

#### 1.11.12.1.9 Field: Simple Buoyancy Stable Tilted Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.10 Field: Simple Buoyancy Unstable Tilted Equation Source**

Applies to zone with no HVAC or when HVAC is off. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choices include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.11 Field: Simple Buoyancy Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.12 Field: Simple Buoyancy Windows Equation Source**

Applies to zone with no HVAC or when HVAC is off. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, KaradagChilledCeiling, ISO15099Windows, or UserCurve.

**1.11.12.1.13 Field: Simple Buoyancy Windows Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.14 Field: Floor Heat Ceiling Cool Vertical Wall Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for vertical walls. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.15 Field: Floor Heat Ceiling Cool Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.16 Field: Floor Heat Ceiling Cool Stable Horizontal Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for passive horizontal surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.17 Field: Floor Heat Ceiling Cool Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.18 Field: Floor Heat Ceiling Cool Unstable Horizontal Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for passive horizontal surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq4CeilingAwayFromHeat, or UserCurve.

**1.11.12.1.19 Field: Floor Heat Ceiling Cool Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.20 Field: Floor Heat Ceiling Cool Heated Floor Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for a floor with active heating elements. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, AwbiHattonHeatedFloor, or UserCurve

**1.11.12.1.21 Field: Floor Heat Ceiling Cool Heated Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.22 Field: Floor Heat Ceiling Cool Chilled Ceiling Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for a ceiling with active cooling elements. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KaradagChilledCeiling, or UserCurve.

**1.11.12.1.23 Field: Floor Heat Ceiling Cool Chilled Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.24 Field: Floor Heat Ceiling Cool Stable Tilted Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, ISO15099Windows, or UserCurve.

**1.11.12.1.25 Field: Floor Heat Ceiling Cool Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.26 Field: Floor Heat Ceiling Cool Unstable Tilted Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, ISO15099Windows, or UserCurve.

**1.11.12.1.27 Field: Floor Heat Ceiling Cool Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.28 Field: Floor Heat Ceiling Cool Window Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.29 Field: Floor Heat Ceiling Cool Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.30 Field: Wall Panel Heating Vertical Wall Equation Source**

Applies to zone with in-wall panel heating. This is for vertical walls that are not actively heated. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq6NonHeatedWalls, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.31 Field: Wall Panel Heating Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.32 Field: Wall Panel Heating Heated Wall Equation Source**

Applies to zone with in-wall panel heating. This is for vertical walls that are being actively heated. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq5WallNearHeat, AwbiHattonHeatedWall, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, or UserCurve.

**1.11.12.1.33 Field: Wall Panel Heating Heated Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.34 Field: Wall Panel Heating Stable Horizontal Equation Source**

Applies to zone with in-wall panel heating. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.35 Field: Wall Panel Heating Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.36 Field: Wall Panel Heating Unstable Horizontal Equation Source**

Applies to zone with in-wall panel heating. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: ASHRAEVerticalWall, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq7Ceiling, or UserCurve

**1.11.12.1.37 Field: Wall Panel Heating Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.38 Field: Wall Panel Heating Stable Tilted Equation Source**

Applies to zone with in-wall panel heating. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, ISO15099Windows, or UserCurve.

**1.11.12.1.39 Field: Wall Panel Heating Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.40 Field: Wall Panel Heating Unstable Tilted Equation Source**

Applies to zone with in-wall panel heating. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, ISO15099Windows, or UserCurve.

**1.11.12.1.41 Field: Wall Panel Heating Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.42 Field: Wall Panel Heating Window Equation Source**

Applies to zone with in-wall panel heating. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.43 Field: Wall Panel Heating Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.44 Field: Convective Zone Heater Vertical Wall Equation Source**

Applies to zone with convective heater. This is for vertical walls not directly affected by heater. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, KhalifaEq6NonHeatedWalls, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve

**1.11.12.1.45 Field: Convective Zone Heater Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.46 Field: Convective Zone Heater Vertical Walls Near Heater Equation Source**

Applies to zone with convective heater. This is for vertical walls that are directly affected by heater. Walls are considered “near” when listed in field set for Fraction of Radiant Energy to Surface. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq5WallNearHeat, AwbiHattonHeatedWall, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.47 Field: Convective Zone Heater Vertical Walls Near Heater Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.48 Field: Convective Zone Heater Stable Horizontal Equation Source**

Applies to zone with convective heater. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.49 Field: Convective Zone Heater Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.50 Field: Convective Zone Heater Unstable Horizontal Equation Source**

Applies to zone with convective heater. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq4CeilingAwayFromHeat, KhalifaEq7Ceiling, or UserCurve.

**1.11.12.1.51 Field: Convective Zone Heater Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.52 Field: Convective Zone Heater Stable Tilted Equation Source**

Applies to zone with convective heater. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.53 Field: Convective Zone Heater Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.54 Field: Convective Zone Heater Unstable Tilted Equation Source**

Applies to zone with convective heater. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.55 Field: Convective Zone Heater Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.56 Field: Convective Zone Heater Windows Equation Source**

Applies to zone with convective heater. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

**1.11.12.1.57 Field: Convective Zone Heater Windows Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.58 Field: Central Air Diffuser Wall Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all wall surfaces. The key choice options include: ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, AlamdariHammondVerticalWall, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve

**1.11.12.1.59 Field: Central Air Diffuser Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.60 Field: Central Air Diffuser Ceiling Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all ceiling surfaces. The key choice options include: FisherPedersenCeilingDiffuserCeiling, BeausoleilMorrisonMixedStableCeiling, BeausoleilMorrisonMixedUnstableCeiling, or UserCurve.

**1.11.12.1.61 Field: Central Air Diffuser Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.62 Field: Central Air Diffuser Floor Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all floor surfaces. The key choice options include: FisherPedersenCeilingDiffuserFloor, BeausoleilMorrisonMixedStableFloor, BeausoleilMorrisonMixedUnstableFloor, GoldsteinNovoselacCeilingDiffuserFloor, or UserCurve.

**1.11.12.1.63 Field: Central Air Diffuser Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.64 Field: Central Air Diffuser Window Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWindow, or UserCurve.

**1.11.12.1.65 Field: Central Air Diffuser Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.66 Field: Mechanical Zone Fan Circulation Vertical Wall Equation Source**

The key choice options include: KhalifaEq3WallAwayFromHeat, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, AlamdariHammondVerticalWall, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve.

**1.11.12.1.67 Field: Mechanical Zone Fan Circulation Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.68 Field: Mechanical Zone Fan Circulation Stable Horizontal Equation Source**

The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.69 Field: Mechanical Zone Fan Circulation Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.70 Field: Mechanical Zone Fan Circulation Unstable Horizontal Equation Source**

The key choice options include: KhalifaEq4CeilingAwayFromHeat, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.71 Field: Mechanical Zone Fan Circulation Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.72 Field: Mechanical Zone Fan Circulation Stable Tilted Equation Source**

The key choice options include: WaltonStableHorizontalOrTilt or UserCurve

**1.11.12.1.73 Field Mechanical Zone Fan Circulation Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.74 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation Source**

The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.75 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.76 Field: Mechanical Zone Fan Circulation Window Equation Source**

The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalW ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWindow, or UserCurve.

**1.11.12.1.77 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.78 Field: Mixed Regime Buoyancy Assisting Flow on Walls Equation Source**

The key choice options include: BeausoleilMorrisonMixedAssistedWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, GoldsteinNovoselacCeilingL or UserCurve.

**1.11.12.1.79 Field: Mixed Regime Buoyancy Assisting Flow on Walls Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.80 Field: Mixed Regime Buoyancy Opposing Flow on Walls Equation Source**

The key choice options include: BeausoleilMorrisonMixedOpposingWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, GoldsteinNovoselacCeilingL or UserCurve

**1.11.12.1.81 Field: Mixed Regime Buoyancy Opposing Flow on Walls Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.11.12.1.82 Field: Mixed Regime Stable Floor Equation Source**

The key choice options include: BeausoleilMorrisonMixedStableFloor, WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

**1.11.12.1.83 Field: Mixed Regime Stable Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.84 Field: Mixed Regime Unstable Floor Equation Source**

The key choice options include: BeausoleilMorrisonMixedUnstableFloor, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.85 Field: Mixed Regime Unstable Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.86 Field: Mixed Regime Stable Ceiling Equation Source**

The key choice options include: BeausoleilMorrisonMixedStableCeiling, WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.11.12.1.87 Field: Mixed Regime Stable Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.88 Field: Mixed Regime Unstable Ceiling Equation Source**

The key choice options include: BeausoleilMorrisonMixedUnstableCeiling, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.11.12.1.89 Field: Mixed Regime Unstable Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.12.1.90 Field: Mixed Regime Window Equation Source**

The key choice options include: GoldsteinNovoselacCeilingDiffuserWindow, ISO15099Windows, or UserCurve.

**1.11.12.1.91 Field: Mixed Regime Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13 SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections**

Options to change the individual convection model equations for dynamic selection when using AdaptiveConvectionAlgorithm. This object is only needed to make changes to the default model selections for any or all of the surface categories. This object is for the outside face, the side of the surface facing away from the thermal zone.

**1.11.13.1 Inputs****1.11.13.1.1 Field: Name**

A unique name for the object

**1.11.13.1.2 Field: Wind Convection Windward Vertical Wall Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPWindward, MoWiTTWindward, DOE2Windward, NusseltJranges, McAdams, Mitchell, Blocken, Emmel, or UserCurve.

**1.11.13.1.3 Field: Wind Convection Windward Equation Vertical Wall User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13.1.4 Field: Wind Convection Leeward Vertical Wall Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPLeeward, MoWiTTLeeward, DOE2Leeward, Emmel, NusseltJranges, McAdams, Mitchell, or UserCurve.

**1.11.13.1.5 Field: Wind Convection Leeward Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13.1.6 Field: Wind Convection Horizontal Roof Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPWindward, MoWiTTWindward, DOE2Windward, NusseltJurges, McAdams, Mitchell, Blocken, Emmel, ClearRoof, or UserCurve.

**1.11.13.1.7 Field: Wind Convection Horizontal Roof User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13.1.8 Field: Natural Convection Vertical Wall Equation Source**

This is for just the natural convection portion of the total film coefficient. This is for vertical walls. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ISO15099Windows, UserCurve, or None.

**1.11.13.1.9 Field: Natural Convection Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13.1.10 Field: Natural Convection Stable Horizontal Equation Source**

This is for just the natural convection portion of the total film coefficient. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, UserCurve, or None.

**1.11.13.1.11 Field: Natural Convection Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.13.1.12 Field: Natural Convection Unstable Horizontal Equation Source**

This is for just the natural convection portion of the total film coefficient. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, UserCurve, or None

**1.11.13.1.13 Field: Natural Convection Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.11.14 SurfaceConvectionAlgorithm:Inside:UserCurve**

This object is used to describe a custom model equation for surface convection heat transfer coefficients. If more than one curve is referenced, or non-blank, then they are all used, and the result is the simple addition of all the curve results.

### 1.11.14.1 Inputs

#### 1.11.14.1.1 Field: Name

Unique name of input object.

#### 1.11.14.1.2 Field: Reference Temperature for Convection Heat Transfer

This field controls the nature of the reference temperature used with convection coefficient when calculating the heat flow at the surface. Select one of the three choices: MeanAirTemperature, AdjacentAirTemperature, SupplyAirTemperature. MeanAirTemperature is the typical application for the classic convection model used with the complete mixing of room air. AdjacentAirTemperature applies when used with Roomair models that account for temperature variations within the zone air and directs the model to use the temperature near the surface rather than the average for the entire zone. SupplyAirTemperature directs the model to use the supply air conditions for the heat transfer conditions.

#### 1.11.14.1.3 Field: Hc Function of Temperature Difference Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of temperature difference. The curve's "x" is absolute value of delta-T (Surface temperature minus air temperature, (C))

#### 1.11.14.1.4 Field: Hc Function of Temperature Difference Divided by Height Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of temperature difference divided by height. The curve's "x" is absolute value of delta-T/Height (Surface temp minus Air temp)/(vertical length scale), (C/m). For an inside face, the vertical length scale is the zone's interior height.

#### 1.11.14.1.5 Field: Hc Function of Air Change Rate Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of air change rate. The curve's "x" is mechanical ACH (Air Changes per hour from mechanical air system), (1/hr)

#### 1.11.14.1.6 Field: Hc Function of Air System Volume Flow Rate Divided by Zone Perimeter Length Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of air change rate divided perimeter scale. Curve's "x" is mechanical system air flow rate ( $m^3/s$ ) divided by zone's length along exterior walls (m).

### 1.11.15 SurfaceConvectionAlgorithm:Outside:UserCurve

This object is used to describe a custom model equation for surface convection heat transfer coefficients. If more than one curve is referenced, or non-blank, then they are all used and the result is the simple addition of all the curve results.

### 1.11.15.1 Inputs

#### 1.11.15.1.1 Field: Name

Unique name of input object.

### 1.11.15.1.2 Field: Wind Speed Type for Curve

This field specifies what sort of wind velocity data should be used in when evaluating the curve in the following field. There are four key choice options. “WeatherFile” directs using the unmodified value from the epw file or design weather data. “HeightAdjust” uses the value from the epw file modified for height above ground, as determined by the z coordinate, using the site terrain and weather station information. “ParallelComponent” uses the value from the epw file modified to take just the velocity component that is parallel to the surface. “ParallelComponentHeightAdjust” uses the height adjusted wind velocity and then computes the parallel component.

### 1.11.15.1.3 Field: Hf Function of Wind Speed Curve Name

This field contains the name of separate performance curve or table object that describes  $h_f$ , the forced convection coefficient, as a function of wind speed. The curve’s “x” is wind speed as defined by the method chosen in the previous field.

### 1.11.15.1.4 Field: Hn Function of Temperature Difference Curve Name

This field contains the name of separate performance curve or table object that describes  $h_n$ , the natural convection coefficient, as a function of temperature difference. Curve’s “x” is absolute value of delta-T (Surface temperature minus air temperature, (C))

### 1.11.15.1.5 Field: Hc Function of Temperature Difference Divided by Height Curve Name

This field contains the name of separate performance curve or table object that describes  $h_n$ , the natural convection coefficient, as a function of temperature difference divided by height. Curve’s “x” is absolute value of delta-T/Height (Surface temp minus Air temp)/(vertical length scale), (C/m). For an outside face the vertical length scale is the exterior facade’s overall height.

## 1.11.16 SurfaceProperty:ConvectionCoefficients

The convection coefficients of each surface, both exterior and interior, are automatically calculated during EnergyPlus execution. These calculations are “governed” by other objects such as the [SurfaceConvectionAlgorithm:Inside](#) (overall default), the Zone object’s field called Zone Inside Convection Algorithm (Zone Default), the and the [SurfaceConvectionAlgorithm:Outside](#) (overall default), and/or the Zone object’s field called Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the “override” convection coefficients in the following object. This object allows for a single surface to be given specific convection coefficients.

Note that using these in conjunction, in particular, the “Simple” option on either the Outside Convection Algorithm or the Zone Outside Convection Algorithm field will result in a combined coefficient regardless of choice chosen here.

Note that surfaces with “[SurfaceProperty:OtherSideCoefficients](#)” cannot use this object with the “outside” coefficient – attempting to do so will cause a severe error; [SurfaceProperty:OtherSideCoefficients](#) surfaces can apply an “inside” coefficient. And, surfaces with “Ground” exposure do not use the “outside” coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. [Window](#)) or certain algorithm types.

### 1.11.16.1 Inputs

#### 1.11.16.1.1 Field: Surface Name

This field is the applicable surface name for the user supplied convection coefficient.

#### 1.11.16.1.2 Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

#### 1.11.16.1.3 Field: Convection Coefficient 1 Location

#### 1.11.16.1.4 Field: Convection Coefficient 2 Location

This field contains the word “Outside” or “Inside” depending on which location is being described.

#### 1.11.16.1.5 Field: Convection Coefficient 1 Type

#### 1.11.16.1.6 Field: Convection Coefficient 2 Type

The entries can be of several types: Value (simple numeric value), Schedule (name of schedule with the values), the usual key choices for overall models for Outside or Inside (Simple, SimpleCombined, TARP, AdaptiveConvectionAlgorithm etc.), the key choices for individual convection equations used for customizing the adaptive algorithm, or a custom user defined correlation. The field should contain one of the keys listed in the table below along with face they can be applied. The definitions of the models and key choices are discussed under [SurfaceConvectionAlgorithm:Inside](#), [SurfaceConvectionAlgorithm:Outside](#), [SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections](#), and [SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections](#).

Key choice	Applies to Inside or Outside

#### 1.11.16.1.7 Field: Convection Coefficient 1

#### 1.11.16.1.8 Field: Convection Coefficient 2

If the Convection type was “Value”, then this field is filled and contains the simple value to be used. Otherwise, this can be blank.

#### 1.11.16.1.9 Field: Convection Coefficient 1 Schedule Name

#### 1.11.16.1.10 Field: Convection Coefficient 2 Schedule Name

If the Convection type was “Schedule”, then this field contains the name of a schedule describing the value to be used during the time intervals for the schedule.

### 1.11.16.1.11 Field: Convection Coefficient 1 User Curve Name

### 1.11.16.1.12 Field: Convection Coefficient 2 User Curve Name

If the Convection type was “UserCurve”, then this field contains the name of a SurfaceConvectionAlgorithm:UserCurve input object describing the model equations to be used during the time intervals for the schedule.

In IDF usage:

## 1.11.17 SurfaceProperty:ConvectionCoefficients:MultipleSurface

The convection coefficients of each surface, both outside and inside, are automatically calculated during EnergyPlus execution. These calculations are “governed” by other objects such as the Inside Convection Algorithm (overall default) and the Zone Inside Convection Algorithm (Zone Default) and the Outside Convection Algorithm (overall default) and/or the Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the “override” convection coefficients in the following object. This object is similar to the preceding “ConvectionCoefficients” object but allows multiple surfaces to be assigned a type with one object entry.

Note that using these in conjunction, in particular, the “Simple” option on either the Outside Convection Algorithm or the Zone Outside Convection Algorithm field will result in a combined coefficient regardless of choice chosen here.

Note that surfaces with “[SurfaceProperty:OtherSideCoefficients](#)” cannot use this object with the “outside” coefficient – attempting to do so will ignore OSC surfaces during a multiple surface “apply”; [SurfaceProperty:OtherSideCoefficients](#) surfaces can apply an “inside” coefficient. And, surfaces with “Ground” exposure do not use the “outside” coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. [Window](#)) or certain algorithm types.

### 1.11.17.1 Inputs

#### 1.11.17.1.1 Field: Surface Type

This field is the applicable surface name for the user supplied convection coefficient. The allowable surface types are:

- AllExteriorSurfaces (all surfaces that are “external environment” surfaces)
- AllExteriorWindows (all windows that are “external environment” surfaces)
- AllExteriorWalls
- AllExteriorRoofs
- AllExteriorFloors
- AllInteriorSurface (all surfaces that are “internal” surfaces)
- AllInteriorWindows
- AllInteriorCeilings
- AllInteriorFloors

#### 1.11.17.1.2 Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

#### 1.11.17.1.3 Field: Convection Coefficient 1 Location

#### 1.11.17.1.4 Field: Convection Coefficient 2 Location

This field contains the word “Outside” or “Inside” depending on which location is being described.

#### 1.11.17.1.5 Field: Convection Coefficient 1 Type

#### 1.11.17.1.6 Field: Convection Coefficient 2 Type

The entries can be of several types: Value (simple numeric value), Schedule (name of schedule with the values), the usual key choices for overall models for Outside or Inside (Simple, SimpleCombined, TARP, AdaptiveConvectionAlgorithm etc.), the key choices for individual convection equations used for customizing the adaptive algorithm, or a custom user defined correlation. The field should contain one of the keys listed in the table below along with face they can be applied. The definitions of the models and key choices are discussed under [SurfaceConvectionAlgorithm:Inside](#) , [SurfaceConvectionAlgorithm:Outside](#), [SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections](#), and [SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections](#).

  Outside,           ! Convection Coefficient 1 Location
  MoWitt;           ! Convection Coefficient 1 Type
```

## 1.11.18 Convection Coefficient Application Hierarchy

Ultimate flexibility and possibly ultimate user confusion can result from the convection coefficient possibilities in EnergyPlus. The objects that control how convection models are assigned to individual surfaces are:

- SurfaceConvectionAlgorithm:Inside
- SurfaceConvectionAlgorithm:Outside
- Zone, Field: Zone Inside Convection Algorithm
- Zone, Field: Zone Outside Convection Algorithm
- SurfaceProperty:ConvectionCoefficients
- SurfaceProperty:ConvectionCoefficients:MultipleSurface

General to Specific, they are assigned in this order:

Table 1.18: Convection Coefficient Assignment Hierarchy

Objects/Description	Action
SurfaceConvectionAlgorithm:*	Assigns for all surfaces in the run.
Zone, Fields: Zone * Convection Algorithm	Trumps global assignment and assigns for all surfaces in Zone.
SurfaceProperty:...:MultipleSurfaces	Trumps above and assigns for specific types of surfaces.
Two Multiple Surface Assignments overlapping (such as AllExteriorSurfaces vs AllExteriorWalls)	Order in IDF is now important. Whichever is first gets the cookie and the second gets a warning.
Specific Surface Assignment	Trumps all Above.

There are additional objects that provide fine control over the models that get assigned.

- SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections
- SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections
- SurfaceConvectionAlgorithm:Inside:UserCurve
- SurfaceConvectionAlgorithm:Outside:UserCurve

## 1.11.19 Convection Coefficients Outputs

Outputs for the User Supplied Convection Coefficients appear as values in the Surface Output Variables (*Surface Inside Face Convection Heat Transfer Coefficient* and *Surface Outside Face Convection Heat Transfer Coefficient*). What the program expects to use is shown in the Surface Details report (*Output:Surfaces>List, Details;*)

When EnergyPlus is set to Display Advanced Variables (*Output:Diagnostics*, *DisplayAdvancedVariables;*), then additional output variables are available that indicate the status of convection modeling by identifying which models are in effect at a given time. The adaptive convection algorithms may switch between models over time and the following output variables provide a way to monitor this behavior. These outputs are integer codes and the integer values are explained in tables.

### 1.11.19.1 Surface Inside Face Convection Classification Index

This variable reports how the surface was classified as part of the adaptive convection algorithm for the inside face. The algorithm examines probable flow regimes, heat flow directions, orientations, HVAC equipment connections, and current operating status to assign each surface a category. The numbers in this report are integer codes that correspond to surface categories as described in the following table.

Code	Zone Airflow Regime	Type of surface	Heat Flow
-1	Invalid	N/A	N/A
1	A1 Radiant Floor or Ceiling Heated Chilled	Vertical Wall	Any

Code	Zone Airflow Regime	Type of surface	Heat Flow	
2	A1 Radiant Floor or Ceiling	Heated Chilled	Horizontal	Stable
3	A1 Radiant Floor or Ceiling	Heated Chilled	Horizontal	Unstable
4	A1 Radiant Floor or Ceiling	Heated Chilled	Heated Floor	Unstable
5	A1 Radiant Floor or Ceiling	Heated Chilled	Chilled Ceiling	Unstable
6	A1 Radiant Floor or Ceiling	Heated Chilled	Tilted	Stable
7	A1 Radiant Floor or Ceiling	Heated Chilled	Tilted	Unstable
8	A1 Radiant Floor or Ceiling	Heated Chilled	Window	Any
9	A2 Radiant Wall Heat	Non-heated Wall	Vertical	Any
10	A2 Radiant Wall Heat	Heated wall	Any	
11	A2 Radiant Wall Heat	Horizontal	Stable	
12	A2 Radiant Wall Heat	Horizontal	Unstable	
13	A2 Radiant Wall Heat	Tilted	Stable	
14	A2 Radiant Wall Heat	Tilted	Unstable	
15	A2 Radiant Wall Heat	Windows	Any	
16	A3 Simple Buoyancy	Vertical Walls	Any	
17	A3 Simple Buoyancy	Horizontal	Stable	
18	A3 Simple Buoyancy	Horizontal	Unstable	
19	A3 Simple Buoyancy	Tilted	Stable	
20	A3 Simple Buoyancy	Tilted	Unstable	
21	A3 Simple Buoyancy	Windows	Any	
22	B Convective Zone Heat	Vertical Walls	Any	
23	B Convective Zone Heat	Vertical Walls near heater	Any	
24	B Convective Zone Heat	Horizontal	Stable	

Code	Zone Airflow Regime	Type of surface	Heat Flow
25	B Convective Heat Zone	Horizontal	Unstable
26	B Convective Heat Zone	Tilted	Stable
27	B Convective Heat Zone	Tilted	Unstable
28	B Convective Heat Zone	Windows	Any
29	C Central Air Diffuser	Walls	Any
30	C Central Air Diffuser	Ceiling	Any
31	C Central Air Diffuser	Floor	Any
32	C Central Air Diffuser	Windows	Any
33	D Zone Fan Unit	Walls	Any
34	D Zone Fan Unit	Horizontal	Stable
35	D Zone Fan Unit	Horizontal	Unstable
36	D Zone Fan Unit	Tilted	Stable
37	D Zone Fan Unit	Tilted	Unstable
38	D Zone Fan Unit	Windows	Any
39	E Mixed Forced and Buoyancy	Walls	Assisting
40	E Mixed Forced and Buoyancy	Walls	Opposing
41	E Mixed Forced and Buoyancy	Floor	Stable
42	E Mixed Forced and Buoyancy	Floor	Unstable
43	E Mixed Forced and Buoyancy	Ceiling	Stable
44	E Mixed Forced and Buoyancy	Ceiling	Unstable
45	E Mixed Forced and Buoyancy	Windows	Any

### 1.11.19.2 Surface Inside Face Convection Model Equation Index

This variable reports the specific model equation used to calculate the inside face convection coefficient. This can vary when using the adaptive convection algorithm and so the result of that selection algorithm is reported here. The following table lists the models associated with specific integer codes reported here. The models correspond to key words used in input objects.

Report Code	Related key and model
200	UserValue
201	UserSchedule
202	UserCurve
203	ASHRAEVerticalWall
204	WaltonUnstableHorizontalOrTilt
205	WaltonStableHorizontalOrTilt

### 1.11.19.3 Surface Inside Face Convection Reference Air Index

The inside face convection heat transfer calculations can be based on different reference air temperatures. This reference air temperature can vary during the simulation when the adaptive algorithm selects models that use different references. The following table lists the meaning of the integer codes.

Report Code	Reference Air Temperature Method
1	Zone mean air temperature
2	Surface adjacent air temperature
3	Supply air temperature

#### 1.11.19.4 Surface Outside Face Convection Classification Index

This variable reports how the surface was classified as part of the adaptive convection algorithm for the outside face. The algorithm examines the wind direction, heat flow directions and orientations to assign each surface a category. The numbers in this report are integer codes that correspond to surface categories as described in the following table.

Report Code	Surface Classification
-1	Invalid
101	Vertical Wall, Windward
102	Vertical Wall, Leeward
103	Roof, stable heat flow direction
104	Roof, unstable heat flow direction

#### 1.11.19.5 Surface Outside Face Forced Convection Model Equation Index

#### 1.11.19.6 Surface Outside Face Natural Convection Model Equation Index

These variables report the specific model equation used to calculate the outside face's convection coefficient. They can vary when using the adaptive convection algorithm and so the results of that selection algorithm are reported in these variables. The following table lists the models associated with specific integer codes that might be reported here. The models correspond to key words used in input objects.

Report Code	Related key and model
300	None
301	UserValue
302	UserSchedule

## 1.11.20 SurfaceProperties:VaporCoefficients

Advanced/Research Usage: The internal and external vapor transfer coefficients that are used by the CombinedHeatAndMoistureFiniteElement model are automatically calculated during EnergyPlus execution using information on the convection coefficients. However it is sometimes useful to be able to “override” the calculation and set fixed values of vapor transfer coefficient for a single surface. These coefficients are only used by the CombinedHeatAndMoistureFiniteElement model and will be ignored by other solution algorithms.

### 1.11.20.1 Inputs

#### 1.11.20.1.1 Field: Surface Name

This field is the applicable surface name for the user supplied vapor transfer coefficient.

#### 1.11.20.1.2 Field: Constant External Vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the external vapor transfer coefficient

#### 1.11.20.1.3 Field: External Vapor Coefficient Value

HAMT will use this value to calculate the vapor transfer into and out off the external surface of this surface. Units are kg/Pa.s.m<sup>2</sup>.

#### 1.11.20.1.4 Field: Constant Internal vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the internal vapor transfer coefficient

#### 1.11.20.1.5 Field: Internal Vapor Coefficient Value

The CombinedHeatAndMoistureFiniteElement algorithm will use this value to calculate the vapor transfer into and out of the internal surface of this surface. Units are kg/Pa.s.m<sup>2</sup>.

Below is an example input of vapor transfer coefficients for a surface.

```

SurfaceProperties:VaporCoefficients,
  South wall,      !- Surface Name
  Yes,           !- Constant External Vapor Transfer Coefficient
  0.000000625,    !- External Vapor Coefficient Value
  Yes,           !- Constant Internal vapor Transfer Coefficient
  0.00000002;     !- Internal Vapor Coefficient Value

```

---

### 1.11.21 SurfaceProperty:ExteriorNaturalVentedCavity

This object is used to model a multi-skin exterior heat transfer surface. This is a special case where the outside face is a slightly detached layer forming a naturally ventilated cavity. The actual outer surface is referred to as the baffle. The modeling here assumes that the heat capacity in the outer baffle can be neglected since it is much lower than the underlying mass surface. This object is used with the [BuildingSurface:Detailed](#) object where the Heat Transfer surfaces are referred to as the underlying surfaces. The constructions and materials for the [BuildingSurface:Detailed](#) object should reflect the construction of just the underlying surface. The SurfaceProperty:ExteriorNaturalVentedCavity object is used to describe the decoupled layer, or baffle, and the characteristics of the cavity and openings for natural ventilation. This object is also used in conjunction with the OtherSideConditionsModel.

The area and orientation are obtained from [BuildingSurface:Detailed](#) objects, which are referenced by name. This object can be used to model certain types of photovoltaic mounting configurations such as interlocking roof pavers. If the baffle covers only part of a surface, then that surface should be split into separate [BuildingSurface:Detailed](#) objects where one matches the size of the baffle. A single baffle can be associated with as many [BuildingSurface:Detailed](#) objects as desired. The base heat transfer surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

Note that the model involves predicting the rates that ambient air moves in and out of the cavity. Accurate modeling of these air flows would be extremely challenging and so the models provided through this object are simplistic engineering models based on discharge coefficients that are sensitive to wind and buoyancy effects. The accuracy depends on the values for, and applicability of, the discharge coefficients and unfortunately little research is available to help characterize these. The models should be considered rudimentary and the user is encouraged to explore different values for the coefficients in attempts to bound the importance of natural ventilation for the cavities. See the Engineering Reference for more details.

#### 1.11.21.1 Inputs

##### 1.11.21.1.1 Field: Name

This field contains a unique name for the ventilated cavity.

##### 1.11.21.1.2 Field: Boundary Conditions Model Name

This field contains the name of an [SurfaceProperty:OtherSideConditionsModel](#) object declared elsewhere in the input file. This will connect the baffle and ventilated cavity to the exterior boundary conditions for the underlying heat transfer surface.

##### 1.11.21.1.3 Field: Area Fraction of Openings

This field is used to enter an area fraction for what part of the baffle consists of openings. The area of the openings will set to the product of this field and the sum of the area of the underlying surfaces.

#### 1.11.21.1.4 Field: Thermal Emissivity of Exterior Baffle Material

This field is used to enter the thermal emissivity of the baffle. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

#### 1.11.21.1.5 Field: Solar Absorptivity of Exterior Baffle

This field is used to enter the solar absorptivity of the baffle. This surface property is for shortwave, solar radiation. The property is used for the front side of the baffle that faces the environment. Darker colors have a higher absorptivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the façade.

#### 1.11.21.1.6 Field: Height Scale for Buoyancy-Driven Ventilation

This field is used to enter a nominal height scale (m) for prediction of ventilation induced by buoyancy. This value ( $\Delta H_{NPL}$ ) is defined as the height from the midpoint of the lower opening to the neutral pressure level. Increasing the value will increase the ventilation rate due to buoyancy.

#### 1.11.21.1.7 Field: Effective Thickness of Cavity Behind Exterior Baffle

This field is used to enter a nominal gap thickness (m) for the collector. If the baffle is corrugated, use the average depth. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

#### 1.11.21.1.8 Field: Ratio of Actual Surface Area to Projected Surface Area

This field is used to enter a factor that accounts for the extra surface area resulting from and uneven baffle surface. Corrugations may be present to help stiffen the baffle or ventilated roofing tiles may have more surface area for convection heat transfer than the underlying surface. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the baffle is flat then this ratio is 1.0. If the baffle is corrugated, then this ratio will be greater than one with a typical value might be 1.165.

#### 1.11.21.1.9 Field: Roughness of Exterior Surface

This field is used to describe the relative roughness of the baffle material. This field is similar to one in the **Material** object. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

#### 1.11.21.1.10 Field: Effectiveness for Perforations with Respect to Wind

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind. Wind will cause exterior air to move in and out of the cavity. Cv is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. Cv should probably be in the range 0.05 to 0.65. Increasing Cv will increase the amount of natural ventilation. The following equation shows how Cv is used in the program to predict the volumetric flow rate due to wind:

$$\dot{V}_{\text{wind}} = C_v A_{\text{in}} U_{\infty} \quad (1.21)$$

### 1.11.21.1.11 Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy. Stack or buoyancy effects will cause exterior air to move in and out of the cavity. Cd is an arbitrary discharge coefficient that depends on the geometry of the opening. Cd should probably be in the range 0.1 to 1.0. Increasing Cd will increase the amount of natural ventilation. The following equations show how Cd is used in the program to predict the volume flow rate due to buoyancy:

$$\dot{V}_{\text{thermal}} = C_D A_{in} \sqrt{2g} \Delta H_{NPL} (T_{a,cav} - T_{amb}) / T_{a,cav} \quad (\text{if } T_{a,cav} > T_{amb})$$

$$\dot{V}_{\text{thermal}} = C_D A_{in} \sqrt{2g} \Delta H_{NPL} (T_{amb} - T_{a,cav}) / T_{amb} \quad (\text{if } T_{amb} > T_{a,cav} \text{ and baffle is vertical})$$

where  $\Delta H_{NPL}$  is the value input into the field above for the height scale for buoyancy-driven ventilation.

### 1.11.21.1.12 Field(s): Surface <1 thru x> Name

The remaining fields are used to name the **BuildingSurface:Detailed** objects that are associated with the exterior naturally vented cavity. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These surfaces should all specify OtherSideConditionsModel as their exterior environment. This object is extensible, so additional fields of this type can be added to the end of this object.

An example IDF entry is

```
SurfaceProperty:ExteriorNaturalVentedCavity,
  PVRoofPaverExtVentCav1 ,      ! Name
  PVRoofPaverSystem1 ,          ! OtherSideConditionsModel Object Name
  0.02,           ! Area Fraction of Openings
  0.9,            ! Thermal Emissivity of Exterior Baffle Material
  0.92,           ! Solar Absorbtivity of Exterior Baffle
  0.05,           ! Height scale for buoyancy-driven ventilation
  0.05,           ! Effective Thickness of Cavity Behind Exterior Baffle
  0.97,           ! Ratio of Actual surface area to projected surface area
  Smooth ,        ! Roughness of collector
  0.1 ,           ! Cv, Effectiveness for perforations with respect to Wind
  0.5 ,           ! Cd, Discharge Coefficient for Openings with respect to buoyancy-driven flow
Zn001:Roof001 ;      ! Surface Name
```

## 1.11.21.2 Outputs

In addition to related output that can be obtained for all surfaces, these outputs are available for exterior naturally vented cavity configurations:

- HVAC,Average, Surface Exterior Cavity Air Drybulb Temperature [C]
- HVAC,Average, Surface Exterior Cavity Baffle Surface Temperature [C]
- HVAC,Average, Surface Exterior Cavity Total Natural Ventilation Air Change Rate [ACH]
- HVAC,Average, Surface Exterior Cavity Total Natural Ventilation Mass Flow Rate [kg/s]
- HVAC,Average, Surface Exterior Cavity Natural Ventilation from Wind Mass Flow Rate [kg/s]
- HVAC,Average, Surface Exterior Cavity Natural Ventilation from Buoyancy Mass Flow Rate [kg/s]

### 1.11.21.2.1 Surface Exterior Cavity Air Drybulb Temperature [C]

The temperature of air inside the cavity behind the baffle.

### 1.11.21.2.2 Surface Exterior Cavity Baffle Surface Temperature [C]

The surface temperature of the exterior baffle material itself.

### **1.11.21.2.3 Surface Exterior Cavity Total Natural Ventilation Air Change Rate [ACH]**

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

### **1.11.21.2.4 Surface Exterior Cavity Total Natural Ventilation Mass Flow Rate [kg/s]**

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

### **1.11.21.2.5 Surface Exterior Cavity Natural Ventilation from Wind Mass Flow Rate [kg/s]**

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

### **1.11.21.2.6 Surface Exterior Cavity Natural Ventilation from Buoyancy Mass Flow Rate [kg/s]**

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to buoyancy-driven forces.

## **1.11.22 SurfaceProperty:SolarIncidentInside**

This object can be used as an alternative to the standard (automatic) EnergyPlus calculation of the solar radiation incident on interior surfaces of the building. Using this method, the normal EnergyPlus calculation is replaced with a schedule of solar incidence values that are calculated outside the program.

### **1.11.22.1 Inputs**

#### **1.11.22.1.1 Field: Name**

The name of the SurfaceProperty:SolarIncidentInside object Must be unique between all SurfaceProperty:SolarIncidentInside objects.

#### **1.11.22.1.2 Field: Surface Name**

The building surface associated with this object (ref [BuildingSurface:Detailed](#)). Solar absorptance values in the schedule file will be applied to the inside of this surface.

#### **1.11.22.1.3 Field: Construction Name**

The building construction associated with this object (ref [Construction](#)). It is possible that the Energy Management System will change the construction associated with the surface; if the construction is changed, a new set of data may need to be applied to the current surface.

#### **1.11.22.1.4 Field: Inside Surface Incident Sun Solar Radiation Schedule Name**

This field specifies the name of a schedule that contains the values for incident solar radiation. Values from the schedule data will be used to replace the absorbed solar radiation that would normally be calculated by EnergyPlus. Units in the external schedule file must be W/m<sup>2</sup>.

Example for SurfaceProperty:SolarIncidentInside using a compact schedule:

```

Schedule:Compact,
  North Wall SSG,          !- Name
  Positive Number,         !- Schedule Type Limits Name
  Through: 12/31,          !- Field 1
  For: AllDays,            !- Field 2
  Until: 07:00,10,          !- Field 3
  Until: 17:00,20,          !- Field 5
  Until: 24:00,15;          !- Field 7

SurfaceProperty:SolarIncidentInside,
  North Wall Solar Incident, !- Name
  Room102 North Wall,        !- Surface Name
  Room Wall - North,         !- Construction Name
  North Wall SSG;           !- Schedule Name

```

## 1.11.23 ComplexFenestrationProperty:SolarAbsorbedLayers

This object can be used as an alternative to the standard (automatic) EnergyPlus calculation of the solar radiation absorbed by fenestration systems in the building. Using this method, the normal EnergyPlus calculation is replaced with a schedule of solar absorptance values that are calculated outside the program.

### 1.11.23.1 Inputs

#### 1.11.23.1.1 Field: Name

The name of the ComplexFenestrationProperty:SolarAbsorbedLayers object Must be unique between all ComplexFenestrationProperty:SolarAbsorbedLayers objects.

#### 1.11.23.1.2 Field: Fenestration Surface

The fenestration surface associated with this object (ref [FenestrationSurface:Detailed](#)). Values from the schedule data will be used to replace the absorbed solar radiation in the fenestration layers that would normally be calculated by EnergyPlus. Value units in the schedule must be W/m<sup>2</sup>.

#### 1.11.23.1.3 Field: Construction Name

The building construction associated with this object (ref [Construction](#)). It is possible that the Energy Management System will change the construction associated with the surface; if the construction is changed, a new set of data may need to be applied to the current surface.

#### 1.11.23.1.4 Field: Layer 1 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains the absorbed solar radiation values in units of W/m<sup>2</sup>. Values from the schedule are used for the absorbed solar radiation of the first (outside) layer.

#### 1.11.23.1.5 Field: Layer 2 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of W/m<sup>2</sup>. Values from the schedule are used for the absorbed solar radiation of the second layer.

#### 1.11.23.1.6 Field: Layer 3 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of W/m<sup>2</sup>. Values from the schedule are used for the absorbed solar radiation for the third layer.

### 1.11.23.1.7 Field: Layer 4 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of W/m<sup>2</sup>. Values from the schedule are used for the absorbed solar radiation of the fourth layer.

### 1.11.23.1.8 Field: Layer 5 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of W/m<sup>2</sup>. Values from the schedule are used for the absorbed solar radiation of the fifth layer.

Example for ComplexFenestrationProperty:SolarAbsorbedLayers with compact schedules:

```

Schedule:Compact,
  Layer 1,          !- Name
  Positive Number, !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,    !- Field 2
  Until: 07:00,1,   !- Field 3
  Until: 17:00,2,   !- Field 5
  Until: 24:00,1.5; !- Field 7

Schedule:Compact,
  Layer 2,          !- Name
  Positive Number, !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,    !- Field 2
  Until: 07:00,0.8, !- Field 3
  Until: 17:00,1.2, !- Field 5
  Until: 24:00,1.0; !- Field 7

Schedule:Compact,
  Layer 3,          !- Name
  Positive Number, !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,    !- Field 2
  Until: 07:00,1,   !- Field 3
  Until: 17:00,2.1, !- Field 5
  Until: 24:00,1.7; !- Field 7

ComplexFenestrationProperty:SolarAbsorbedLayers,
  South Window Solar Absorbed Layers, !- Name
  Room 102 South Window,           !- Fenestration surface name
  CFS_Glz_2,                      !- Construction Surface name
  Layer 1,                         !- Absorbed solar energy in layer 1
  Layer 2,                         !- Absorbed solar energy in layer 2
  Layer 3;                        !- Absorbed solar energy in layer 3

```

## 1.11.24 GeometryTransform

This object provides a simple method of altering the footprint geometry of a model. The intent is to provide a single parameter that can be used to reshape the building description contained in the rest of the input file. This object was implemented for use in parametric massing studies and with the optimization program GenOpt. Although building footprint is often constrained in practice, analysts may find this object useful for investigating how building form impacts daylighting and solar gains on the east and west facades without having to change all of the surface geometry input.

Aspect Ratio is defined as the overall length in the East-West direction divided by the overall length in the North-South direction.

This object should be used with considerable care since it will completely alter the geometry modeled by EnergyPlus and may have unintended side effects. The surface areas of all horizontal surfaces may

change radically with corresponding changes in Zone floor areas. The total floor area will not change but individual horizontal surfaces will gain and loose area. Vertical surfaces will have the same height but will gain and lose length. Lighting and electrical equipment design levels for individual zones will likely have a different energy per unit area in the transformed geometry.

The surface geometry must be set to **Relative**, see [GlobalGeometryRules](#). Of course, the coordinates must be entered in relative coordinates as well.

Since windows in EnergyPlus need to be rectangular, it is possible to define a horizontal window (skylight) that once transformed is no longer rectangular and will cause EnergyPlus to halt. To avoid this problem, horizontal windows should be defined orthogonal to the Cardinal directions and building rotation (see [Building](#)) used to orient the final form with respect to North.

The object doesn't create any specific output, but the results of using it can be understood by viewing DXF output files. Figure 1.64 shows an example of a building that has been morphed using the Aspect Ratio Transform object. Using this object allowed the same geometry input to generate both of the models represented in by their DXF output files.

### 1.11.24.1 Inputs

#### 1.11.24.1.1 Field: Plane of Transform

This field specifies the plane that the geometry transform should act on. It is currently restricted to altering the horizontal footprint of a building and must be set to "XY."

#### 1.11.24.1.2 Field: Current Aspect Ratio

This field specifies the aspect ratio of the building geometry described in the rest of the input file. It is used to scale the new aspect ratio. If this field is set to 1.0, then the altered building will not necessarily have the new aspect ratio defined in the next field.

#### 1.11.24.1.3 Field: New Aspect Ratio

This field specifies the aspect ratio that the building described in the rest of the input file will be changed to.

## 1.11.25 SurfaceProperty:SurroundingSurfaces

The object is used to calculate long wave radiation to an external surface from its surrounding surfaces, defining the properties of the surrounding surfaces. The property object declares a list of single surrounding surfaces which has a name, a field of view factor, and another field Temperature Schedule Name referencing a schedule containing the temperature of the surrounding surface, which can be overwritten at each time step in EnergyPlus run time through co-simulation. View factors are assumed to be constant values. At least one surrounding surface should be defined in this object.

The object also defines the sky and ground temperature and view factors to the external surface. The sum of all defined view factors should not exceed 1.0. If only sky view is defined in this object, the ground view factor to this surface will be 1.0 subtracted with the ground view factor and all other defined surface view factors. If only ground view is defined in this object, the sky view factor to this surface will be 1.0 subtracted with the sky view factor and all other defined surface view factors. If neither of the sky and ground view factors are explicitly declared here, the sum of the sky and ground view factor would be 1.0 subtracted with all other defined surface view factors and the proportion will be set as the same with the global setting.

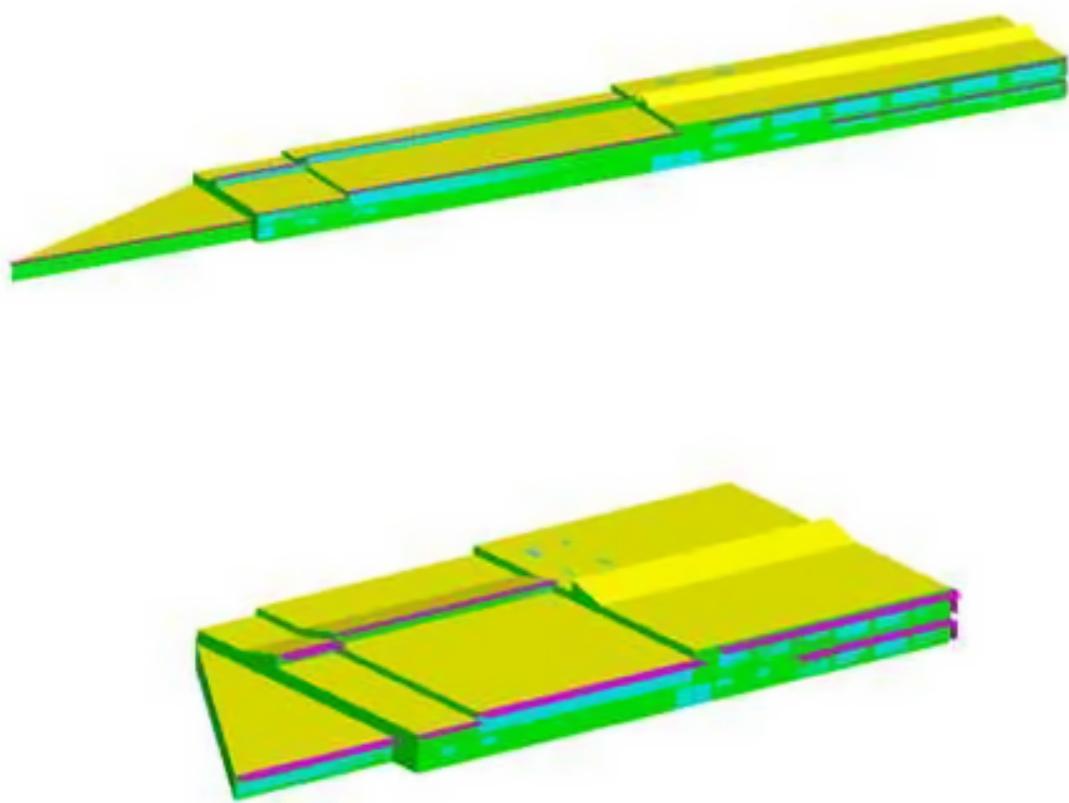

Figure 1.64: Example of Geometry Transform – Aspect Ratio

### 1.11.25.1 Field: Name

This is the unique name of the surface property.

### 1.11.25.2 Field: Sky View Factor

This field defines the constant sky view factor to an external surface. The sky view factor used in solar radiation calculation of the surface would be overwritten with the value of the fraction if defined here. If the field is left blank, the sky view factor of this surface will be calculated with the rules demonstrated above.

### 1.11.25.3 Field: Sky Temperature Schedule Name

This field is used to supply a schedule name of the sky temperature. The sky temperature used in solar radiation calculation of the surface would be overwritten with the value of the scheduled temperature if defined here. If the field is left blank, the global sky temperature would be used.

### 1.11.25.4 Field: Ground View Factor

This field defines the constant ground view factor to an external surface. The ground view factor used in solar radiation calculation of the surface would be overwritten with the value of the fraction if defined here. If the field is left blank, the ground view factor of this surface will be calculated with the rules demonstrated above.

### 1.11.25.5 Field: Ground Temperature Schedule Name

This field is used to supply a schedule name of the ground temperature. The ground temperature used in solar radiation calculation of the surface would be overwritten with the value of the scheduled temperature if defined here. If the field is left blank, the global ground temperature would be used.

### 1.11.25.6 Field: Surrounding Surface 1 Name

This field defines the name of a surrounding surface to the external surface.

### 1.11.25.7 Field: Surrounding Surface 1 View Factor

This field defines the constant view factor of a surrounding surface to an external surface.

### 1.11.25.8 Field: Surrounding Surface 1 Temperature Schedule Name

This field is used to supply a schedule name of the of a surrounding surface temperature.

The object is extensible so the last three fields can be repeated to define multiple surrounding surface name, temperature and view factor sets.

An example IDF object follows.

```
SurfaceProperty:SurroundingSurfaces,
  SrdSurfs:Window,          !- Name
  0.3,                      !- Sky View Factor
  ,                         !- Sky Temperature Schedule Name
  0.1,                      !- Ground View Factor
  ,                         !- Ground Temperature Schedule Name
  SurroundingSurface1,      !- Surrounding Surface 1 Name
  0.6,                      !- Surrounding Surface 1 View Factor
  Surrounding Temp Sch 1;   !- Surrounding Surface 1 Temperature Schedule Name
```

```

Schedule:Compact,
Surrounding Temp Sch 1,      !- Name
Any Number,                   !- Schedule Type Limits Name
Through: 12/31,               !- Field 1
For: AllDays,                 !- Field 2
Until: 24:00, 15.0;          !- Field 3

```

## 1.11.26 SurfaceProperty:LocalEnvironment

The object links to a surface object **Surface:Detailed** and is used when there is a need to calculate surface level environmental data externally and import them into the simulation to override existing environmental data, including external solar shading fractions, local air velocity, temperature and humidity, and surrounding surface temperatures and view factors. The object links to three optional objects including a schedule object declared by **Field: External Shading Fraction Schedule Name**, a **SurfaceProperty:SurroundingSurfaces** object declared by **Field: Surrounding Surfaces Object Name**, and an **OutdoorAir:Node** object declared by **Field: Outdoor Air Node Name**. The object provides inputs to calculate shading, solar radiation, zone air balance and surface exterior heat balance.

### 1.11.26.1 Field: Name

This is the unique name of the surface property.

### 1.11.26.2 Field: Surface Name

This is the name of the surface that will be assigned to use the local environmental data defined in the next three fields. This should be a name of a surface defined elsewhere.

### 1.11.26.3 Field: External Shading Fraction Schedule Name

This field is used to import external shading fraction data from external calculation. This should be a name of a schedule object with fraction input.

### 1.11.26.4 Field: Surrounding Surfaces Object Name

This field is used to import surrounding surfaces properties (temperature and view factors to the external surface) from external calculation. This should be a name of a **SurfaceProperty:SurroundingSurfaces** object.

### 1.11.26.5 Field: Outdoor Air Node Name

This field is used to import local environmental data from local outdoor air nodes, including dry and wet bulb temperature, wind speed and wind direction. This should be a name of a **OutdoorAir:Node** object.

An example IDF object follows.

```

SurfaceProperty:LocalEnvironment,
LocEnv:Zn001:Wall001,        !- Name
Zn001:Wall001,               !- Exterior Surface Name
ExtShadingSch:Zn001:Wall001, !- External Shading Fraction Schedule Name
SrdSurf:Zn001:Wall001,       !- Surrounding Surfaces Object Name
OutdoorAirNode:0001;         !- Outdoor Air Node Name

```

## 1.11.27 ZoneProperty:LocalEnvironment

The object links to a **Zone** object and is used when there is a need to calculate zone level environmental data externally and import them into the simulation to override existing environmental data, including local air temperature and humidity, wind velocity and direction. links to an **OutdoorAir:Node** object declared by **Field: Outdoor Air Node Name**. The reference local outdoor air node provides ambient conditions for the calculation of infiltration and ventilation at the zone level.

### 1.11.27.1 Field: Name

This is the unique name of the zone property.

### 1.11.27.2 Field: Zone Name

This is the name of the zone that will be assigned to use the local environmental data defined in the next field. This should be a name of a surface defined elsewhere.

### 1.11.27.3 Field: Outdoor Air Node Name

This field is used to import local environmental data from local outdoor air nodes, including dry and wet bulb temperature, wind speed and wind direction. This should be a name of a **OutdoorAir:Node** object.

An example IDF object follows.

```
ZoneProperty:LocalEnvironment,
  LocEnv:Zn001,           !- Name
  Zn001,                  !- Exterior Surface Name
  OutdoorAirNode:0001;    !- Outdoor Air Node Name
```

---

## 1.11.28 SurfaceProperty:HeatBalanceSourceTerm

The object allows additional heat source term of the surface boundary condition in the surface heat balance calculation. The object specifies a surface with the additional heat source term described by a schedule of heat rates (can be positive or negative values) in W/m<sup>2</sup>. A heat source can be added to either or both the inside and outside of the same surface. The heat rates are pre-calculated outside EnergyPlus.

### 1.11.28.1 Field: Surface Name

This is the name of the surface that will be assigned to use the additional heat source term in heat balance calculation

### 1.11.28.2 Field: Inside Face Heat Source Term Schedule Name

The value of this schedule is the source term value for the inside face of this surface. If this field is left blank, no inside surface source term will be applied. The schedule values are heat rate per surface area (W/m<sup>2</sup>), when positive schedule values indicate heat gain and negative values indicates loss.

### 1.11.28.3 Field: Outside Face Heat Source Term Schedule Name

The value of this schedule is the source term value for the outside face of this surface. If this field is left blank, no outside surface source term will be applied. The schedule values are heat rate per surface area (W/m<sup>2</sup>), when positive schedule values indicate heat gain and negative values indicates loss.

```

SurfaceProperty:HeatBalanceSourceTerm,
  Zn001:Wall001,           !- Surface Name
  ,                         !- Inside Face Heat Source Term Schedule Name
  HeatSourceSch:001;        !- Outside Face Heat Source Term Schedule Name

```

---

## 1.11.29 Zone Property View Factors

EnergyPlus has two options for specifying the thermal radiation exchange view factors between surfaces in a zone: the approximate option and the user input option. Because the actual geometric arrangement within a zone is very complex, the approximate method of including thermal mass and other forced exchanges is more realistic than trying to come up with “exact” view factors. However, in some research situations it might be desirable to have control of the view factors used. For this reason, a user input mode has been included in EnergyPlus. The two modes are described in the next sections.

### 1.11.29.1 Approximate Option

The first option produces approximate results and uses an area weighted scheme to calculate “view factors” between surfaces within a thermal zone. Each surface uses the total area that it can “see” among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that are visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt (“same” being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surfaces is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be “around the corner” from each other and in reality not see each other at all. Rooms are assumed to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1, 3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

### 1.11.29.2 User Input View Factors

The second option for specifying view factors requires user input values. These should be used with care in research or special situations. The object available for this is [ZoneProperty:UserViewFactors:BySurfaceName](#).

### 1.11.30 ZoneProperty:UserViewFactors:BySurfaceName

The method of entering user view factors is to enter each surface name and its view factor value to other surfaces in a radiant/solar enclosure which may consist of one space, one zone or a group of spaces or zones.

#### 1.11.30.1 Inputs

##### 1.11.30.1.1 Field: Zone or ZoneList or Space or SpaceList Name

An enclosure for radiant exchange may be a single space or zone, or a group of spaces or zones connected by one or more air boundaries (see [Construction:AirBoundary](#)). An enclosure may also be a group of spaces in the same zone with implied air boundaries because the spaces are defined only by floor surfaces (see [Space](#)). If a ZoneList name is specified, the referenced “[ZoneList](#)” must match a group of zones connected with Construction:AirBoundary.

Enter the applicable surface pairs with non-zero view factors. Any omitted surface pair is assumed to have a zero view factor.

##### 1.11.30.1.2 Field: From Surface 1

This field specifies the name of the “from surface”.

##### 1.11.30.1.3 Field: To Surface 1

This field specifies the name of the “to surface”.

##### 1.11.30.1.4 Field: Factor 1

This value is the view factor for “from Surface” to “to Surface”.

An IDF Example:

```
ZoneProperty:UserViewFactors:BySurfaceName,Lshaped Zone,
  Lshaped Zone:South Wall,Lshaped Zone:South Wall,0.000000,
  Lshaped Zone:South Wall,Lshaped Zone:East Wall,0.101310,
<snip>
```

## 1.12 Group – Detailed Ground Heat Transfer

### 1.12.1 Detailed Ground Heat Transfer

The following objects may be included in an EnergyPlus input IDF file but are handled by the Slab preprocessor:

- [GroundHeatTransfer:Slab:Materials](#)
- [GroundHeatTransfer:Slab:MatlProps](#)
- [GroundHeatTransfer:Slab:BoundConds](#)
- [GroundHeatTransfer:Slab:BldgProps](#)
- [GroundHeatTransfer:Slab:Insulation](#)
- [GroundHeatTransfer:Slab:EquivalentSlab](#)
- [GroundHeatTransfer:Slab:AutoGrid](#)
- [GroundHeatTransfer:Slab:ManualGrid](#)
- [GroundHeatTransfer:Slab:XFACE](#)
- [GroundHeatTransfer:Slab:YFACE](#)
- [GroundHeatTransfer:Slab:ZFACE](#)

The following objects may be included in an EnergyPlus input IDF file but are handled by the Basement preprocessor:

- GroundHeatTransfer:Basement:SimParameters
- GroundHeatTransfer:Basement:MatlProps
- GroundHeatTransfer:Basement:Insulation
- GroundHeatTransfer:Basement:SurfaceProps
- GroundHeatTransfer:Basement:BldgData
- GroundHeatTransfer:Basement:Interior
- GroundHeatTransfer:Basement:ComBldg
- GroundHeatTransfer:Basement:EquivSlab
- GroundHeatTransfer:Basement:EquivAutoGrid
- GroundHeatTransfer:Basement:AutoGrid
- GroundHeatTransfer:Basement:ManualGrid
- GroundHeatTransfer:Basement:XFACE
- GroundHeatTransfer:Basement:YFACE
- GroundHeatTransfer:Basement:ZFACE

The documentation both the Slab and Basement objects appear in the AuxiliaryPrograms document under the “Ground Heat Transfer in EnergyPlus” heading.

The only object described in this section is the control object which activates the use of the preprocessor.

## 1.12.2 GroundHeatTransfer:Control

The GroundHeatTransfer:Control object determines if the Slab and Basement preprocessors are going to be executed. When a Slab or Basement run is performed the results are saved in files with extensions .SLAB or .BSMT so that they do not need to be rerun if no input changes are made to the GroundHeatTransfer:Slab or GroundHeatTransfer:Basement objects.

### 1.12.2.1 Inputs

#### 1.12.2.1.1 Field: Name

This alpha field is the name of the GroundHeatTransfer:Control object. It is used as an identifier.

#### 1.12.2.1.2 Field: Run Basement Preprocessor

The field can either be Yes or No and defaults to No. It is used to control whether the Basement preprocessor program is executed. If it has been previously executed the results are stored in the .BSMT file and do not necessary need to be run again unless the GroundHeatTransfer:Basement objects have changed.

#### 1.12.2.1.3 Field: Run Slab Preprocessor

The field can either be Yes or No and defaults to No. It is used to control whether the Slab preprocessor program is executed. If it has been previously executed the results are stored in the .SLAB file and do not necessary need to be run again unless the GroundHeatTransfer:Slab objects have changed.

## 1.13 Group – Room Air Models

### 1.13.1 Room Air Models

The group of input objects described in this section is used to account for non-uniform room air temperatures that may occur within the interior air volume of a zone. Room air modeling was added to EnergyPlus starting with Version 1.2. Although there are many types of analyses (comfort, indoor air quality, etc) that might benefit from localized modeling of how room air varies across space, only the *temperature* distribution of room air within the zone is currently addressed in EnergyPlus. This allows surface heat transfer and air system heat balance calculations to be made taking into account natural thermal stratification of air and different types of intentional air distribution designs such as under-floor and side-wall displacement ventilation that purport to extract room air at higher-than-mean temperatures. Note that EnergyPlus does **not** have completely general methods of modeling room air that are applicable to every conceivable type of airflow that might occur in a zone. Such models (e.g. RANS-CFD) are too computationally expensive to use with EnergyPlus for the foreseeable future. The models that are available in EnergyPlus offer only limited modeling capabilities for select room airflow configurations. Also note that because the complete mixing model for room air has long been the standard in building energy simulation, there is not currently a consensus on how to best model non-uniform air temperatures in buildings. Therefore, it is up to the user to have a good understanding of when, where, and how to apply the room air models available in EnergyPlus. The rest of this section provides some guidance in the way of examples and further discussion of the models available in EnergyPlus.

EnergyPlus offers the different types of air models listed in the table below along with the input objects associated with the use of that model.

Table 1.24: Summary of Room Air Models

Air Model Key	Air model Algorithm	Applicability	Input Objects Required
Mixing	Well-Mixed	All zones	None, default
UserDefined	User Defined	All zones	‘RoomAirModelType’, ‘RoomAir:Temperature- Pattern:UserDefined’, ‘RoomAir:Temperature- Pattern:***’
OneNodeDisplacement- Ventilation	Mundt	displacement ventilation	‘RoomAirModelType’, ‘RoomAirSettings:OneNode- DisplacementVentilation’, ‘RoomAir:Node’
ThreeNodeDisplacement- Ventilation	UCSD Ventilation	Displacement	displacement ventilation ‘RoomAirModelType’, ‘RoomAirSettings:Three- NodeDisplacement- Ventilation’
UnderFloorAirDistribution- Interior	UCSD UFAD Interior Model	Interior zones served by a UFAD system	‘RoomAirModelType’, ‘RoomAirSettings:Under- FloorAirDistributionInterior’
UnderFloorAirDistribution- Exterior	UCSD UFAD Exterior Model	Exterior zones served by a UFAD system	‘RoomAirModelType’, ‘RoomAirSettings:Under- FloorAirDistribution- Exterior’
CrossVentilation	UCSD Cross Ventilation	cross ventilation	‘RoomAirModelType’, ‘RoomAirSettings:Cross- Ventilation’

### 1.13.2 RoomAirModelType

EnergyPlus uses the RoomAirModelType object to determine which air model is available for use in a given zone during the simulation. If no RoomAirModelType object is specified (for each zone or the whole

building), then EnergyPlus will run with the conventional, completely mixing air model (for each zone or the whole building). Include a RoomAirModelType for each zone that the user wants modeled using a more detailed method. Currently only a single RoomAirModelType object can be specified for each zone; you cannot switch between models during a simulation. However, the UCSD Displacement, Cross Ventilation and UFAD models switch from displacement to mixing ventilation when the operating conditions do not give rise to unmixed flow. The following parameters are fields required by the RoomAirModelType object.

### 1.13.2.1 Inputs

### 1.13.2.1.1 Field: Name

This alpha field is the air model name selected by user. It is used as an identifier

#### 1.13.2.1.2 Field: Zone Name

This alpha field indicates the unique name of a Zone object defined elsewhere in the input file. The type of room air model selected will be applied to this zone.

### 1.13.2.1.3 Field: Room-Air Modeling Type

This alpha field indicates the room-air model used for the specified zone. Currently, there are three options for different air models. Entering the keyword ‘Mixing’ specifies the conventional complete-mixing air model. Note that Mixing is the default and no RoomAirModelType object would be needed to use the complete-mixing model. Entering the keyword ‘UserDefined’ specifies the User Defined Room Air Temperature Patterns. Entering the keyword ‘OneNodeDisplacementVentilation’ specifies the Mundt one node displacement ventilation air model for displacement ventilation. Entering the keyword ‘ThreeNodeDisplacementVentilation’ specifies the three-node displacement ventilation model developed by the University of California, San Diego (UCSD DV). Entering the keyword ‘CrossVentilation’ specifies the two-zone cross ventilation model developed by the University of California, San Diego (UCSD CV). Entering the keyword ‘UnderFloorAirDistributionInterior’ specifies the two-node interior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFI). Entering the keyword ‘UnderFloorAirDistributionExterior’ specifies the two-node exterior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFE).

#### 1.13.2.1.4 Field: Air Temperature Coupling Strategy

This alpha field indicates how air temperatures predicted by the air models are used by the surface heat balance calculation. Two different coupling schemes are available: Direct (also known as *T-couple*) or Indirect (*DT-couple*). In general, indirect coupling is more suited to situations where room air is well controlled and/or the room air model is less robust. Direct coupling is more suited for floating zone air temperatures and/or accurate room air models.

The Mundt model can use either coupling scheme; the UCSD DV, UCSD CV, UCSD UFI, and UCSD UFE models ignore this field and use direct coupling.

Input either *Direct* or *Indirect*

An example idf entry follows

### 1.13.3 RoomAir:TemperaturePattern:UserDefined

This object is used to explicitly define temperature patterns that are to be applied to the mean air temperature within a thermal zone. This Room Air modeling option is made available for a number of reasons. It allows modeling the consequences of air temperature variations during the design phase when little information is available about the specifics of the air distribution system or positioning of various loads. This option can be used to evaluate the energy implications of different design targets for the temperature patterns. It also provides a method of modeling the annual energy use implications for air temperature distributions determined using separate analyses or measurements. For example, this option could be used to understand the annual energy implications of an air distribution system that has been previously analyzed using Computational Fluid Dynamics.

This approach differs from the other Room Air modeling in that the static temperature pattern is not really *modeled* so that it will respond to conditions that develop during the simulation. More sophisticated dynamic Room Air models will adjust the temperature pattern based on various factors, such as air system flow rate, floor temperature, or rates of internal heat gains. The user-defined temperature distribution patterns are fixed at the beginning and EnergyPlus simply provides results that include the implications of those patterns. This user-defined distribution option may also be useful for checking dynamic Room Air models by using “bounding” analysis.

Note that using this object carries a certain degree of responsibility. It would be very easy to define a pattern that is non-physical and will lead to erroneous results. The user-defined temperature distributions should (probably) be balanced about the mean so that basic conservation of energy laws are not violated.

#### 1.13.3.1 Inputs

##### 1.13.3.1.1 Field: Name

This field provides a unique name for this object.

##### 1.13.3.1.2 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file.

##### 1.13.3.1.3 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this model is available. When not available the room air is modeled as completely mixed. When it is available, then a user-defined temperature distribution will be applied. This schedule should be set to “1.0” when model is available and “0.0” when the model is not to be used. If this field is blank, the schedule has values of 1 for all time periods.

##### 1.13.3.1.4 Field: Pattern Control Schedule Name

This field provides the name of schedule that will be used to control which user-defined RoomAir temperature pattern will be applied at any given time. This schedule needs to have integer values that are closely coordinated with those defined as the second field in one of the RoomAir:TemperaturePattern:\* objects described below. These schedule values provide the link to the actual patterns to be used throughout the day. This allows controlling which user-defined pattern is used at different times during the simulation. For example, one could use one pattern when the air system is scheduled to be on, and a different pattern when the air system is scheduled to be off. Or if the user has knowledge of how the air temperature pattern changes over the course of day in response to changing thermal loads, then this schedule can be used to control when individual patterns are used. For example, a control schedule could use a pattern designated as number 100 from 18:00 to 6:00, pattern number 200 from 6:00 to 12:00, and pattern number 300 from 12:00 to 18:00.

An example of this object is

```

RoomAir:TemperaturePattern:UserDefined,
Ground Floor South Air Temp Controls, ! Name
ZN2_S_1, ! Zone Name
Always_on, ! Availability Schedule Name
Roomair Pattern 1; ! Pattern Control Schedule Name

```

---

## 1.13.4 RoomAir:TemperaturePattern:ConstantGradient

This object is used to model room air with a fixed temperature gradient in the vertical direction. This fixed-slope method is about the simplest distribution pattern.

In addition to the vertical temperature gradient, there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

One example of a source of input data for the vertical temperature gradient is ANSI/ASHRAE Standard 55-2004 Thermal Environmental Conditions for Human Occupancy. Table 5.2.4.3 in this Standard specifies an allowable vertical temperature difference between head level and ankle level of 3°C (5°F). If we assume a head to ankle length scale of 1.5 m (5 ft), this leads to a temperature gradient of 3°C/1.5m, or 2.0 °C/m.

### 1.13.4.1 Inputs

#### 1.13.4.1.1 Field: Name

This field provides a unique name for this object.

#### 1.13.4.1.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:\* objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

#### 1.13.4.1.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

#### 1.13.4.1.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

#### 1.13.4.1.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

#### 1.13.4.1.6 Field: Temperature Gradient

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °K/m.

An example of this object is:

```

RoomAir:TemperaturePattern:ConstantGradient,
half C per Meter,      ! Name
10005,                 ! Control Integer for Pattern Control Schedule Name
0.0,                   ! Thermostat Offset (Temp at thermostat- Mean Air Temp) [C]
1.0,                   ! Return Air Offset (Tleaving - Mean Air Temp ) [C]
1.0,                   ! Exhaust Air Offset (Texhaust - Mean Air Temp) [C]
0.5;                  ! Temperature Gradient [K/m]

```

---

## 1.13.5 RoomAir:TemperaturePattern:TwoGradient

This object provides various controls over the value of the gradient used for determining the pattern of room air temperatures. It is similar to previous object [RoomAir:TemperaturePattern:ConstantGradient](#) object but simplifies the potentially arduous task of preparing and scheduling a large number of those objects. With this object, two different gradients are entered and user is given several options for controlling how the program will interpolate between the two bounds. The user inputs the height of the location of thermostat, return air, and exhaust air in meters rather than the temperature offset.

### 1.13.5.1 Inputs

#### 1.13.5.1.1 Field: Name

This field provides a unique name for this object.

#### 1.13.5.1.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:<sup>\*</sup> objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

#### 1.13.5.1.3 Field: Thermostat Height

This field specifies the distance above the floor where the thermostat is situated. This height is used by the model to determine the thermostat temperature relative to the mean air temperature by applying the gradient.

#### 1.13.5.1.4 Field: Return Air Height

This field specifies the distance above the floor where the air leaves the zone and returns to the air system. and the mean air temperature. This height is used by the model to determine the return air temperature relative to the mean air temperature by applying the gradient.

#### 1.13.5.1.5 Field: Exhaust Air Height

This field specifies the distance above the floor where the air leaves the zone and enters and exhaust device such as an exhaust fan. This height is used by the model to determine the exhaust air temperature relative to the mean air temperature by applying the gradient.

#### 1.13.5.1.6 Field: Temperature Gradient Lower Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

#### 1.13.5.1.7 Field: Temperature Gradient Upper Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

#### 1.13.5.1.8 Field: Gradient Interpolation Mode

This field specifies how the program will vary between the two gradients. Select one of the following keywords to choose the simulation data used to scale: ‘Outdoor Environment Drybulb Temperature’, ‘Zone Drybulb Temperature’, ‘Delta Outdoor and Zone Temperature’, ‘Sensible Cooling Load’, and ‘Sensible Heating Load’. These are explained in detail below. All of these options have several things in common. They are essentially hard-coded. There is no support for a general method. The interpolation scheme is based on some variable that might reasonably be expected to correlate with gradient changes. This variable’s current value is used to continually adjust the value of the vertical gradient for room air temperature.

**OutdoorDryBulbTemperature:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the outdoor air temperature. If the outdoor temperature exceeds the upper limit set in the next field, then the gradient entered in the ‘Temperature Gradient Upper Bound’ field is used. Similarly if the outdoor air temperature is below the value set in the ‘Lower Temperature’ field, then the gradient entered in the ‘Temperature Gradient Lower Bound’ is used. For outdoor temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**ZoneDryBulbTemperature:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the mean zone air temperature. If the mean zone air temperature exceeds the upper limit set in the next field, then the gradient entered in the ‘Temperature Gradient Upper Bound’ field is used. Similarly if the mean zone air temperature is below the value set in the ‘Lower Temperature’ field, then the gradient entered in the ‘Temperature Gradient Lower Bound’ is used. For mean zone air temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**ZoneAndOutdoorTemperatureDifference:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the difference between the outdoor environment and the mean zone air temperature. If the temperature difference exceeds the upper limit set in the next field, then the gradient entered in the ‘Temperature Gradient Upper Bound’ field is used. Similarly if the temperature difference is below the value set in the ‘Lower Temperature’ field, then the gradient entered in the ‘Temperature Gradient Lower Bound’ is used. For temperature differences that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**SensibleCoolingLoad:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible cooling load. If the cooling load exceeds the upper limit set in the next field, then the gradient entered in the ‘Temperature Gradient Upper Bound’ field is used. Similarly if the cooling load is below the value set in the ‘Lower Temperature’ field, then the gradient entered in the ‘Temperature Gradient Lower Bound’ is used. For cooling loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**SensibleHeatingLoad:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible heating load. If the heating load exceeds the upper limit set in the next field, then the gradient entered in the ‘Temperature Gradient Upper Bound’ field is used. Similarly if the heating load is below the value set in the ‘Lower Temperature’ field, then the gradient entered in the ‘Temperature Gradient Lower Bound’ is used. For heating loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

#### 1.13.5.1.9 Field: Upper Temperature Bound

This field is used to enter the upper bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

#### 1.13.5.1.10 Field: Lower Temperature Bound

This field is used to enter the lower bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

#### 1.13.5.1.11 Field: Upper Heat Rate Bound

This field is used to enter the upper bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

#### 1.13.5.1.12 Field: Lower Heat Rate Bound

This field is used to enter the lower bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

An example of this object follows. This pattern will apply no gradient (effectively the mixing model) if zone air temperatures are 22.5 C or lower. It will apply a gradient of 1 K/m if zone temperatures are 26.0 C or higher. For zone air temperatures between 22.5 and 26.0 it will determine the gradient by linear interpolation and use a gradient between 0.0 and 1.0 K/m depending on where the zone air temperature is in the range.

```
RoomAir:TemperaturePattern:TwoGradient,
Mixed to one C per M by Zone DB, ! Name
2002,                      ! Control Integer for Pattern Control Schedule

,                            ! Upper Heat Rate [W]
;                            ! Lower Heat Rate [W]
```

#### 1.13.5.2 Outputs

The user-defined air temperature pattern that interpolates between two gradients produces the following output variable.

```
HVAC,Average,Room Air Zone Vertical Temperature Gradient [K/m]
```

##### 1.13.5.2.1 Room Air Zone Vertical Temperature Gradient [K/m]

This output variable is the result of the interpolation performed by the user-defined roomair model using RoomAir:TemperaturePattern:TwoGradient. This is the temperature gradient in the vertical direction. The units are degrees Kelvin per meter.

#### 1.13.6 RoomAir:TemperaturePattern:NondimensionalHeight

This object defines a distribution pattern for air temperatures relative to the current mean air temperature as a function of height. The height, referred to as Zeta, is non-dimensional by normalizing with the zone ceiling height. (The actual zone ceiling height can be explicitly entered in the ‘Zone’ object but if not it is calculated by EnergyPlus from the surfaces attached to the zone.) The temperature differences are not non-dimensional and remain in units of degrees Celsius.

An example of a vertical temperature pattern is shown in the figure below. The pattern itself is treated as a piecewise, linear model of air temperature as a function of height. This Zeta-DeltaTai curve, or lookup table, is then mapped to surfaces defined elsewhere in the file. The centroid of each surface and zone ceiling height are used to automatically assign Zeta values within the program. The zone named in the referencing

`RoomAir:TemperaturePattern:UserDefined` object is used to determine which surfaces will be associated with the pattern when it is applied. A single pattern object can be reused for multiple zones and times.

In addition to the vertical temperature pattern there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

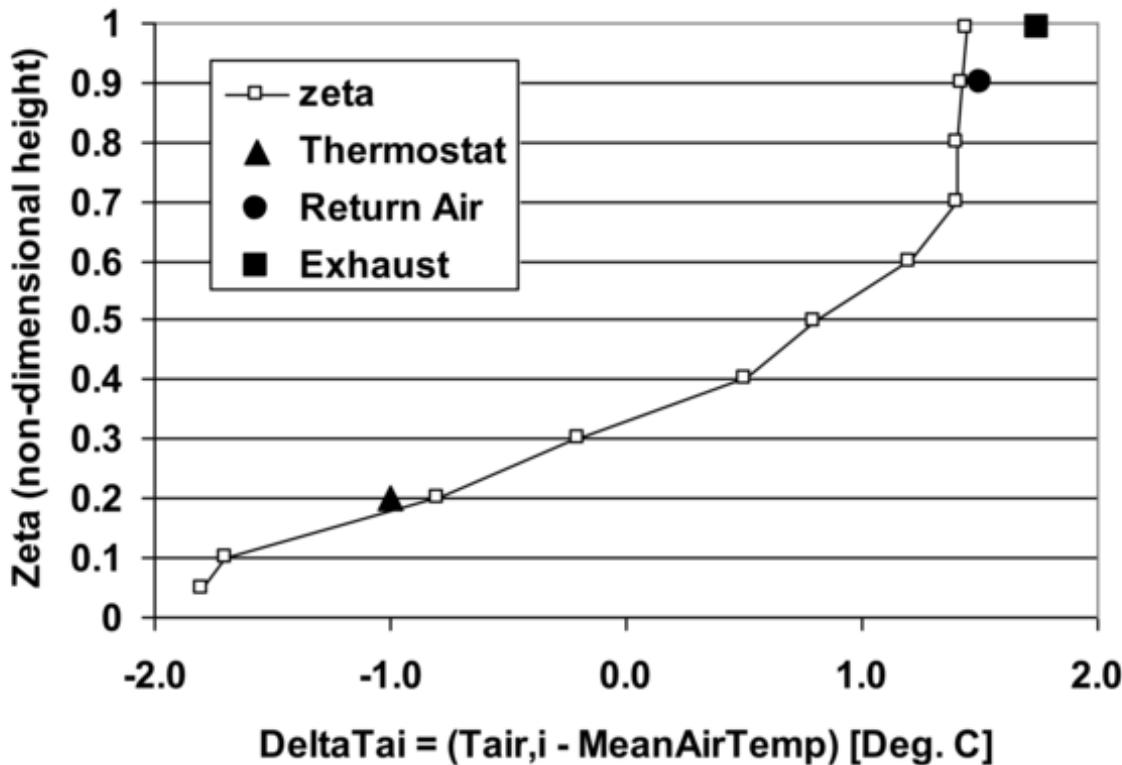

Figure 1.65: Example of a Vertical Air Temperature Pattern

### 1.13.6.1 Inputs

#### 1.13.6.1.1 Field: Name

This field provides a unique name for this object.

#### 1.13.6.1.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

### 1.13.6.1.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

### 1.13.6.1.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

### 1.13.6.1.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

### 1.13.6.1.6 Field Set Zeta and Temperature Difference

The remaining fields contain pairs of values that define a lookup table for the temperature pattern in the vertical direction. The first value is Zeta and the second value is DeltaTai.

### 1.13.6.1.7 Field: Pair <#> Zeta non-dimensional Height

Zeta is the normalized height and should be a fractional value from 0.0 to 1.0. A value of 0.0 corresponds to the floor and a value of 1.0 corresponds to the ceiling. The Zeta values need to be in increasing value.

### 1.13.6.1.8 Field: Pair <#> Delta Adjacent Air Temperature

$\Delta T_{ai}$  is the temperature difference between the air temperature at the associated Zeta ( $T_{ai}$ ) and the mean air temperature and is given in degrees Celsius.

This object is extensible, so additional pairs of these last two fields of this type can be added to the end of this object. An example of this object corresponding to the figure above is:

```
RoomAir:TemperaturePattern:NondimensionalHeight,
Rough UFAD Approx,      ! Name
3001,                   ! Control Integer for Pattern Control Schedule
                        ! note reference this entry in Schedule
-1.0 ,                 ! Thermostat Offset
1.5 ,                  ! Return Air Offset (Tleaving - Mean Air Temp ) deg C
1.75,                  ! Exhaust Air Offset (Texhaust - Mean Air Temp) deg C
0.05, -1.8,            ! pair 1 (Zeta , DeltaTai)
0.1, -1.7,             ! pair 2 (Zeta , DeltaTai)
0.2, -0.8,             ! pair 3 (Zeta , DeltaTai)
0.3, -0.2,             ! pair 4 (Zeta , DeltaTai)
0.4, 0.5,              ! pair 5 (Zeta , DeltaTai)
0.5, 0.8,              ! pair 6 (Zeta , DeltaTai)
0.6, 1.2,              ! pair 7 (Zeta , DeltaTai)
0.7, 1.4,              ! pair 8 (Zeta , DeltaTai)
0.8, 1.4,              ! pair 9 (Zeta , DeltaTai)
0.9, 1.42,             ! pair 10 (Zeta , DeltaTai)
0.95, 1.44;            ! pair 11 (Zeta , DeltaTai)
```

## 1.13.7 RoomAir:TemperaturePattern:SurfaceMapping

This object defines a distribution pattern for the air temperatures adjacent to individual surfaces. This object uses the specific names of individual surfaces defined elsewhere in the model. This pattern allows controlling the adjacent air temperature on a surface-by-surface basis rather than by height. This allows modeling different adjacent air temperatures on the opposite sides of the zone.

In addition to the surface mappings there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of

a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

### 1.13.7.1 Inputs

#### 1.13.7.1.1 Field: Name

This field provides a unique name for this object.

#### 1.13.7.1.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the RoomAir Temperature Distribution.

#### 1.13.7.1.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

#### 1.13.7.1.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

#### 1.13.7.1.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

#### 1.13.7.1.6 Field Set: Surface Name, Temperature Difference

#### 1.13.7.1.7 Fields (6 and on): Pairs of Surface Names and Temperature Differences

The remaining fields contain pairs that define a lookup table for the temperature pattern on a surface-by-surface basis.

#### 1.13.7.1.8 Field: Surface Name Pair <#>

The name of a surface defined elsewhere in the input file.

#### 1.13.7.1.9 Field: Delta Adjacent Air Temperature Pair <#>

$\Delta T_{ai}$  is the temperature difference between the air temperature adjacent to the associated surface ( $T_{ai}$ ) and the mean air temperature and is given in degrees Celsius.

This object is extensible, so additional pairs of fields of these types can be added to the end of this object. An example of this object, which might be used to elevate temperatures near west windows in the afternoon, is:

```
RoomAir:TemperaturePattern:SurfaceMapping,
  GroundFloor SW Corner Hot Near West Wall, ! Name
  4001, ! Control Integer for Pattern Control Schedule Name
  0.0, ! Thermostat Offset(Temp at thermostat- Mean Air Temp)
  0.0, ! Return Air Offset deg C
  0.0, ! Exhaust Air Offset
```

```

## 1.13.8 RoomAir:Node

The RoomAir:Node object is used to define air nodes for a nodal air model. The number of air node objects that need to be specified depends on the nodal air model selected. (However, currently only the Mundt model uses this object). In order to use the Mundt model, the user must specify six or more RoomAir:Node objects of different types for each zone. The exact number of RoomAir:Node in the model will vary based on the resolution of walls. If walls (heat transfer surfaces) are split into separate segments in the vertical direction, then more air nodes of type ‘MundtRoom’ will be useful. At a minimum, for the Mundt model RoomAir Nodes of the following type are required: ‘Inlet’, ‘Floor’, ‘Control’, ‘Ceiling’, ‘MundtRoom’, and ‘Return.’

### 1.13.8.1 Inputs

#### 1.13.8.1.1 Field: Name

This alpha field is a name for the air node. It should be unique and is used as an identifier

#### 1.13.8.1.2 Field: Node Type

This alpha field indicates the type of this air node. The following explains options available for use with the Mundt nodal air model.

**Inlet** is specified for the air node located where the system air enters the zone.

**Floor** is specified for the air node located near the floor.

**Control** is specified for the air node located near the thermostat.

**Ceiling** is specified for the air node located near the ceiling.

**MundtRoom** is specified for the air node located adjacent to the wall(s).

**Return** is specified for the air node located where the system air leaves the zone.

#### 1.13.8.1.3 Field: Zone Name

This field indicates the name of the zone (Ref: Zone) that this air node belongs to. This should be the unique name of a zone object defined elsewhere in the input file.

#### 1.13.8.1.4 Field: Height of Nodal Control Volume Center

This numeric field indicates the height of the air node center. Air models such as the Mundt model compute the air temperature as a function of height and the value entered here will be used to determine a result for this node. The value should be specified in meters and relative to the floor of the zone.

#### 1.13.8.1.5 Field: Surface <#> Name

These remaining alpha fields indicate the names of the surfaces (Ref: Surface) that are interacting convectively with this air node. This field is optional and related to the previous field. Currently, at most 20 surfaces are allowed to interact with a single air node. Only those nodes that interact with the inside faces of surfaces need to specify surface names. Each surface should couple to no more than 1 node.

An IDF example:

```

RoomAir:Node,
  WESTZN:FLOORAIR,      !- Node Name
  Floor,                 !- Node Type
  WEST ZONE,             !- Name of Zone to Which the Air Node Belongs
  0.1,                   !- Height of Nodal Control Volume Center {m}
  WESTZN:FLOOR:LEFF,    !- surface name
  WESTZN:FLOOR:RIGHT;   !- surface name

```

---

## 1.13.9 RoomAirSettings:OneNodeDisplacementVentilation

The RoomAirSettings:OneNodeDisplacementVentilation object is used to specify additional input parameters required by the Mundt model that are not available in other input objects in EnergyPlus. A single object will be used for the zone.

### 1.13.9.1 Inputs

#### 1.13.9.1.1 Field: Zone Name

This alpha field indicates the name of the zone (Ref: Zone) for the required input parameters as specified in the following fields.

#### 1.13.9.1.2 Field: Fraction of Convective Internal Loads Added to Floor Air

This numeric field indicates what fraction of the convective part of the internal gains is added to the air near the floor in the zone specified.

#### 1.13.9.1.3 Field: Fraction of Infiltration Internal Loads Added to Floor Air

This numeric field indicates what fraction of the infiltration air enters near the floor in the zone specified.

An IDF example:

```

RoomAirSettings:OneNodeDisplacementVentilation,
  WEST ZONE,           !- Zone Name
  0.1,                 !- Fraction of internal loads from the convective Floor Air
  0.1;                !- Fraction of internal loads from the Infiltration Air

```

---

### 1.13.9.2 Outputs

The following output is available for the Mundt model.

```
Room Air Node Air Temperature {[}C{]}
```

---

#### 1.13.9.2.1 Room Air Node Air Temperature [C]

This output variable provides the drybulb air temperature used in, or calculated by, the Mundt model. The selection key is the name of an air node defined in a ROOMAIR Node object.

## 1.13.10 RoomAirSettings:ThreeNodeDisplacementVentilation

This model is applicable to spaces that are served by a low velocity floor-level displacement ventilation air distribution system. Furthermore, the dominant sources of heat gain should be from people and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts three temperatures in the room:

- A foot level temperature ( $T_{FLOOR}$ ). The floor region is 0.2 meters deep and  $T_{FLOOR}$  represents the temperature at the mid-point of the region.
- An occupied subzone temperature ( $T_{OC}$ ), representing the temperature in the region between the floor layer and the upper, mixed layer.
- An upper node representing the mixed-layer/outflow temperature ( $T_{MX}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

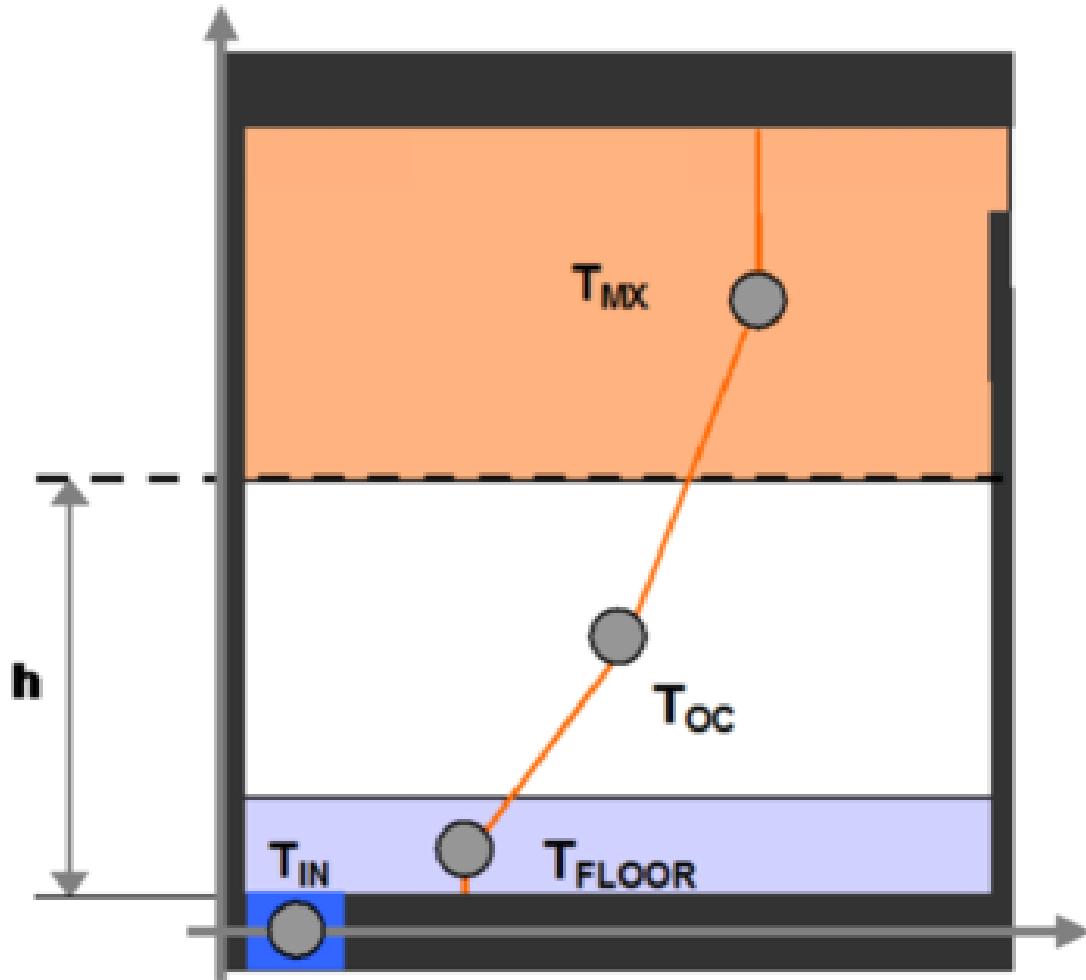

Figure 1.66: Schematic representation of the three temperature points and temperature gradients

The following fields are used to define an instance of the ‘UCSD Displacement Ventilation Model Controls’ object.

#### 1.13.10.1 Inputs

##### 1.13.10.1.1 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the ‘UCSD Displacement Ventilation Model Controls’ object is needed for each zone that is to be modeled using this method.

#### 1.13.10.1.2 Field: Gain Distribution Schedule Name

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values are the fractions of the convective portion of the internal gains in the occupied subzone that remain in the occupied subzone. The remainder of the convective portion of the internal gains in the occupied subzone enters the plumes and is carried to the upper subzone. The types of internal gains that are assumed to be located in the occupied subzone are:

- people
- task lights
- electric equipment
- gas equipment
- hot water equipment
- steam equipment
- other equipment
- baseboard heat

Types of internal gains that are assumed to be in the upper subzone are:

- general lights
- tubular daylighting devices
- high temperature radiant heaters

The schedule values should be between 0 and 1. A value of 1 means that all the convection gains from equipment, task lights and people are dispersed in the lower occupied subzone. Conversely a value of 0 puts all the lower subzone convective gains into the plumes rising into the upper well-mixed subzone.

#### 1.13.10.1.3 Field: Number of Plumes per Occupant

This field specifies number of plumes per occupant. Plumes are associated with localized sources of convective heat gain from people and equipment. For example, a value of 2.0 would be used if each occupant has a computer that generates a separate plume that does not merge with the plume from the occupant in the lower, occupied, subzone.

#### 1.13.10.1.4 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor.

#### 1.13.10.1.5 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. The default is 1.1 meters.

### 1.13.10.1.6 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper mixed subzone and the occupied subzone that will be used to trigger whether or not the displacement ventilation auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height*, *Room Air Zone Recommended Minimum Flow Fraction*, *Room Air Zone Average Temperature Gradient* and *Room Air Zone Maximum Temperature Gradient*. They are set to negative values when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

An example input:

```
RoomAirSettings:ThreeNodeDisplacementVentilation,
  ZONE ONE, !- Zone Name
  Constant - .2, !- Gain Distribution Schedule Name
  1, !- Number of Plumes per Occupant
  , !- Thermostat Height
  , !- Comfort Height
  .3; !- Temp. Difference Threshold for Displacement Ventilation
```

---

### 1.13.10.2 Outputs

- HVAC,Average,Room Air Zone Mixed Subzone Temperature [C]
- HVAC,Average,Room Air Zone Occupied Subzone Temperature [C]
- HVAC,Average,Room Air Zone Floor Subzone Temperature [C]
- HVAC,Average,Room Air Zone Transition Height [m]
- HVAC,Average,Room Air Zone Recommended Minimum Flow Fraction
- HVAC,Average,Room Air Zone Is Mixed Status
- HVAC,Average,Room Air Zone Average Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Maximum Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Thermal Comfort Effective Air Temperature [C]
- HVAC,Average,Room Air Zone Thermostat Temperature [C]

#### 1.13.10.2.1 Room Air Zone Mixed Subzone Temperature [C]

The temperature of the upper well-mixed subzone in degrees C.

#### 1.13.10.2.2 Room Air Zone Occupied Subzone Temperature [C]

The average temperature of the lower, stratified, occupied subzone in degrees C.

#### 1.13.10.2.3 Room Air Zone Floor Subzone Temperature [C]

The temperature of the region near the floor in degrees C.

#### 1.13.10.2.4 Room Air Zone Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper well-mixed subzone.

#### **1.13.10.2.5 Room Air Zone Recommended Minimum Flow Fraction []**

The ratio of the minimum recommended flow rate to the actual flow rate. Here flow rate means the sum of infiltration, ventilation, mixing and system air flow rates. The minimum flow is the flow needed to establish the boundary between the occupied and mixed subzones at 1.5 meters.

#### **1.13.10.2.6 Room Air Zone Is Mixed Status []**

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD DV model used). The value 1 means well-mixed; 0 means stratified.

#### **1.13.10.2.7 Room Air Zone Average Temperature Gradient [K/m]**

The temperature gradient between the middle of the floor region and the middle of the well-mixed upper subzone in degrees Kelvin per meter.

#### **1.13.10.2.8 Room Air Zone Maximum Temperature Gradient [K/m]**

The maximum of the temperature gradient between the middle of the floor region and the middle of the occupied subzone and the temperature gradient between the middle of the occupied subzone and the middle of the well-mixed subzone. The gradient is in degrees Kelvin per meter.

#### **1.13.10.2.9 Room Air Zone Thermal Comfort Effective Air Temperature [C]**

The temperature at the user specified comfort height in degrees C.

#### **1.13.10.2.10 Room Air Zone Thermostat Temperature [C]**

The temperature at the height of the thermostat (specified by user input) in degrees C.

### **1.13.11 RoomAirSettings:CrossVentilation**

The UCSD Cross Ventilation Room Air Model provides a simple model for heat transfer and temperature prediction in cross ventilated rooms. Cross Ventilation (CV) is common in many naturally ventilated buildings, with air flowing through windows, open doorways and large internal apertures across rooms and corridors in the building.

The CV model is used in EnergyPlus in the context of natural ventilation simulations using the AirflowNetwork airflow prediction model. Typical CV room flows are characterized by two clearly distinguishable flow regions that have different airflow velocities and temperature:

- Jet regions in front of the inflow windows
- Recirculation regions in the portions of the room that are not directly in front of the windows.

Each inflow aperture has one jet region while the recirculation regions are treated as a whole, with a single temperature and characteristic velocity. The default EnergyPlus perfectly mixed single temperature node room air approach is not suitable for these partially mixed flows. The proposed CV model uses multiple nodes with distinct air temperature and airflow velocity (one node for the recirculations plus one additional node for each inflow aperture).

The following fields are used to define an instance of the ‘UCSD Cross Ventilation Model Controls’ object.

#### **1.13.11.1 Inputs**

##### **1.13.11.1.1 Field: Zone Name**

This field provides the name of the zone to which this object applies. A single instance of the ‘UCSD Cross Ventilation Model Controls’ object is needed for each zone modeled using this method.

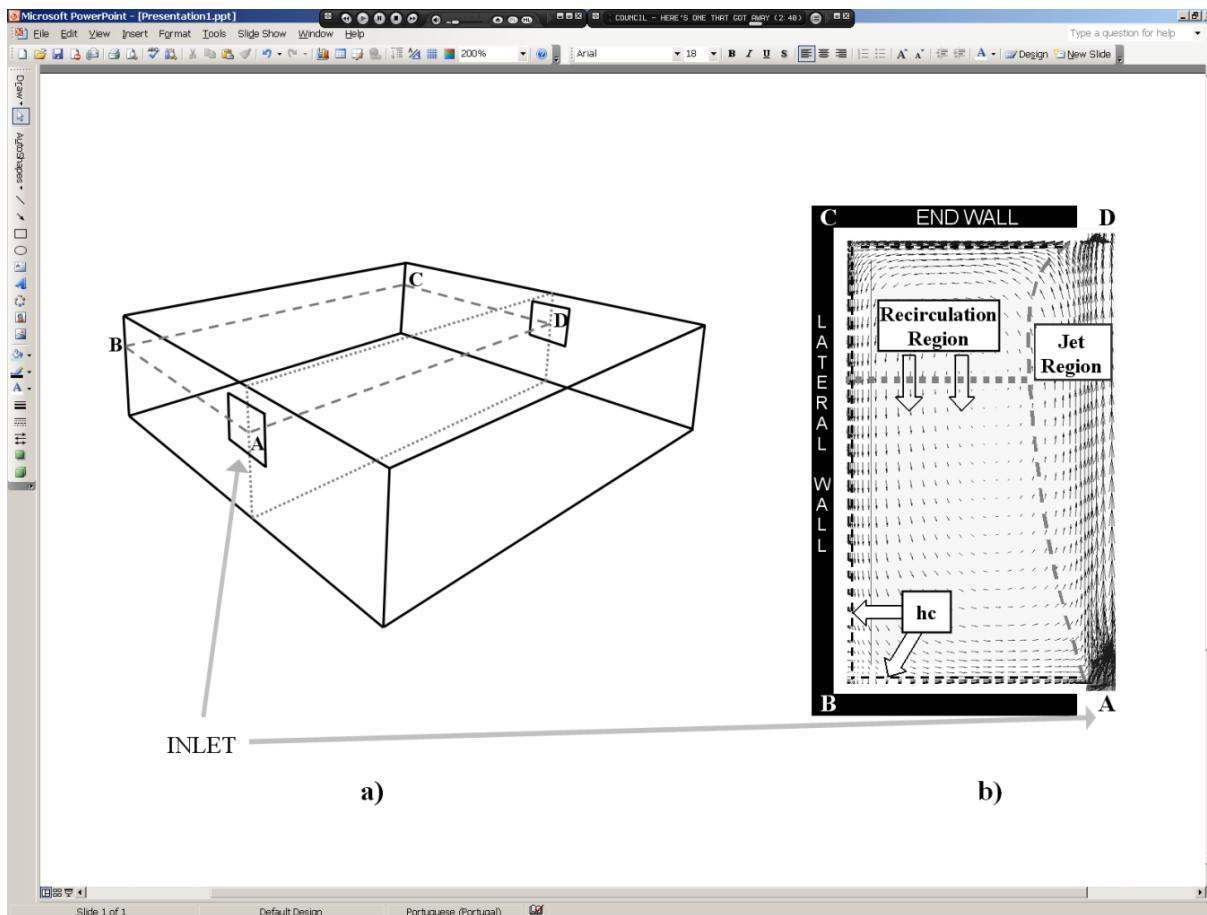

Figure 1.67: Schematic representation of room air geometry a) schematic representation of a room geometry that generates cross ventilation airflow. b) the proposed model distinguishes two regions in the flow: jet and recirculation (shown here in a CFD simulation of one half of a symmetrical room).

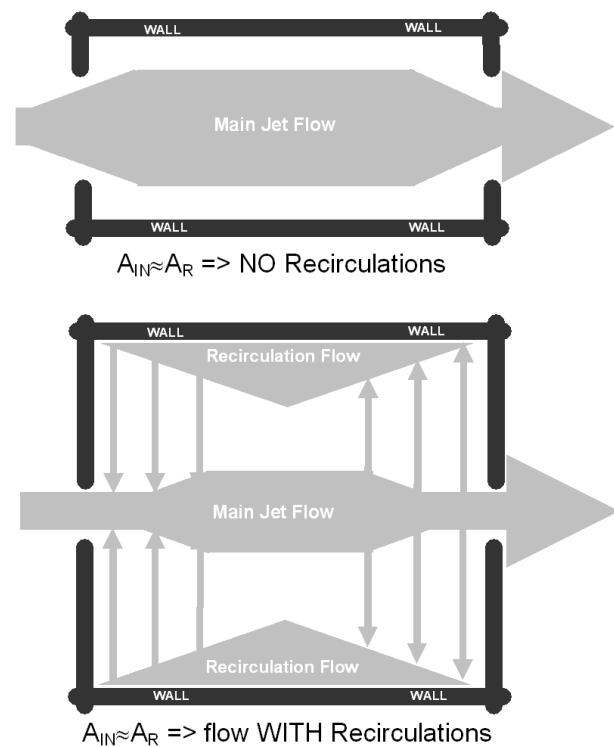

Figure 1.68: Schematic top view — possible airflow patterns in cross-ventilation.

### 1.13.11.1.2 Field: Gain Distribution Schedule Name

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values define the fractions of the convective portion of the internal gains in the jet and recirculation regions.

The schedule values should be between 0 and 1. A value of 1 means that all the convective gains are dispersed in the jet region. Conversely a value of 0 puts all the convective gains into the recirculation region.

### 1.13.11.1.3 Field: Airflow Region Used for Thermal Comfort Evaluation

Required field whenever thermal comfort is predicted. Defines air temperature and mean airflow velocity that will be used in the Fanger model. Conditions must refer to one of the two regions defined in the model: jet or recirculation.

Possible choices: Jet or Recirculation.

## 1.13.11.2 Outputs

- Zone,Average,Room Air Zone Jet Region Temperature [C]
- Zone,Average,Room Air Zone Recirculation Region Temperature [C]
- Zone,Average,Room Air Zone Jet Region Average Air Velocity [m/s]
- Zone,Average,Room Air Zone Recirculation Region Average Air Velocity [m/s]
- Zone,Average,Room Air Window Jet Region Average Air Velocity [m/s]
- Zone,Average,Room Air Zone Recirculation and Inflow Rate Ratio
- Zone,Average,Room Air Zone Inflow Opening Area [m<sup>2</sup>]
- Zone,Average,Room Air Zone Room Length [m]
- Zone,Average,Room Air Zone Is Mixing Status
- Zone,Average,Room Air Zone Is Recirculating Status

### 1.13.11.2.1 Room Air Zone Jet Region Temperature [C]

Average air temperature in the jet region of the flow in degrees C. If there is more than one inflow window this output will be the inflow-area-weighted average of the jet region temperature.

### 1.13.11.2.2 Room Air Zone Recirculation Region Temperature [C]

Average air temperature in the recirculation region of the flow in degrees C.

### 1.13.11.2.3 Room Air Zone Jet Region Average Air Velocity [m/s]

Average airflow velocity in the jet region of the flow in meters per second. If there is more than one inflow window this output will be the inflow area weighted area of the jet inflow velocities.

### 1.13.11.2.4 Room Air Window Jet Region Average Air Velocity [m/s]

Average airflow velocity in the jet region in front of the window, in meters per second.

### 1.13.11.2.5 Room Air Zone Recirculation Region Average Air Velocity [m/s]

Average airflow velocity in the recirculation region of the flow in meters per second.

**1.13.11.2.6 Room Air Zone Recirculation and Inflow Rate Ratio []**

Ratio between airflow rate in the recirculation regions and the total inflow rate, non-dimensional.

**1.13.11.2.7 Room Air Zone Inflow Opening Area [m<sup>2</sup>]**

Area of the inflow aperture in square meters. This area can change due to variation in wind direction (as inflow aperture changes) or variations in the opening schedule.

**1.13.11.2.8 Room Air Zone Room Length [m]**

Length of the room along the cross ventilation direction, in meters.

**1.13.11.2.9 Room Air Zone Is Mixing Status []**

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or significant momentum conservation is occurring (UCSD CV model used). The value 1 means well-mixed; 0 means cross ventilation is present. Transition to mixed flow can occur due to three mechanism: reduction in inflow velocity, reduction in inflow aperture area and dominance of buoyancy effects. A value of 1 is yes, a value of 0 is no.

**1.13.11.2.10 Room Air Zone Is Recirculating Status []**

An integer flag that indicates whether recirculations are present in the flow. A cross ventilation flow does not have recirculations whenever the inflow area is similar to the room cross section area (such as airflow in a typical corridor). A value of 1 is yes, a value of 0 is no.

**1.13.12 RoomAirSettings:UnderFloorAirDistributionInterior**

This model is applicable to interior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts two temperatures in the room:

- An occupied subzone temperature ( $T_{OC}$ ), representing the temperature in the region between the floor and the boundary of the upper subzone.
- An upper subzone temperature ( $T_{MX}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the ‘UCSD UFAD Interior Model Controls’ object.

**1.13.12.1 Inputs****1.13.12.1.1 Field: Zone Name**

This field provides the unique name of a zone described elsewhere in the file. A single instance of the ‘RoomAirSettings:UnderFloorAirDistributionInterior’ object is needed for each zone that is to be modeled using this method.

**1.13.12.1.2 Field: Number of Diffusers**

The total number of diffusers in this zone. This field can allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft<sup>2</sup>. The default for this field is Autocalculate.

### 1.13.12.1.3 Field: Power per Plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is Autocalculate.

### 1.13.12.1.4 Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m<sup>2</sup>, for variable area diffusers 0.035 m<sup>2</sup>, for horizontal swirl diffusers 0.006 m<sup>2</sup>, and for linear bar grilles 0.03 m<sup>2</sup>. The default is *Autocalculate..*

### 1.13.12.1.5 Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

### 1.13.12.1.6 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

### 1.13.12.1.7 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. The default is 1.1 meters.

### 1.13.12.1.8 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height* and *Room Air Zone Average Temperature Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

### 1.13.12.1.9 Field: Diffuser Type

The choices for this alpha field are **Swirl** | **VariableArea** | **HorizontalSwirl** | **LinearBarGrille** | **Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zonesand are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

### 1.13.12.1.10 Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

### 1.13.12.1.11 Field: Coefficient A

The coefficient A in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.12.1.12 Field: Coefficient B

The coefficient B in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.12.1.13 Field: Coefficient C

The coefficient C in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.12.1.14 Field: Coefficient D

The coefficient D in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.12.1.15 Field: Coefficient E

The coefficient E in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.12.2 Outputs

- HVAC,Average,Room Air Zone Mixed Subzone Temperature [C]
- HVAC,Average,Room Air Zone Occupied Subzone Temperature [C]
- HVAC,Average,Room Air Zone Transition Height [m]
- HVAC,Average,Room Air Zone Is Mixed Status []
- HVAC,Average,Room Air Zone Average Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Effective Comfort Air Temperature [C]
- HVAC,Average,Room Air Zone Thermostat Temperature [C]
- HVAC,Average,Room Air Zone Transition Height Gamma Value []
- HVAC,Average,Room Air Zone Plume Heat Transfer Rate [W]
- HVAC,Average,Room Air Zone Temperature Stratification Fraction []

#### 1.13.12.2.1 Room Air Zone Mixed Subzone Temperature [C]

The temperature of the upper subzone in degrees C.

#### 1.13.12.2.2 Room Air Zone Occupied Subzone Temperature [C]

The temperature of the lower, occupied subzone in degrees C.

#### 1.13.12.2.3 Room Air Zone Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper subzone..

#### 1.13.12.2.4 Room Air Zone Is Mixed Status []

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD UFI model used). The value 1 means well-mixed; 0 means stratified.

#### 1.13.12.2.5 Room Air Zone Average Temperature Gradient [K/m]

The temperature gradient between the middle of the occupied subzone and the middle of the upper subzone in degrees Kelvin per meter.

#### 1.13.12.2.6 Room Air Zone Effective Comfort Air Temperature [C]

The temperature at the user specified comfort height in degrees C.

#### 1.13.12.2.7 Room Air Zone Thermostat Temperature [C]

The temperature at the height of the thermostat (specified by user input) in degrees C.

### 1.13.12.2.8 Room Air Zone Transition Height Gamma Value []

Value of gamma – a dimensionless “height” used in calculating the transition height. Lower values of gamma indicate increased stratification, higher values less. Generally the values should be between 2 and 30.

### 1.13.12.2.9 Room Air Zone Plume Heat Transfer Rate [W]

The heat in watts driving the plumes in the occupied subzone.

### 1.13.12.2.10 Room Air Zone Temperature Stratification Fraction []

This output, (Phi) is a measure of temperature stratification in the space. It is the difference between the occupied subzone temperature and the supply temperature divided by difference between the return temperature and the supply temperature. Technically it is equal to Kc. As phi approaches 1, the space is fully mixed. As phi approaches 0, the space becomes fully stratified. Expressed as an equation:

$$\frac{T_{occ} - T_{sup}}{T_{ret} - T_{sup}} \quad (1.22)$$

## 1.13.13 RoomAirSettings:UnderFloorAirDistributionExterior

This model is applicable to exterior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room, as well as convective gain coming from a warm window. The model predicts two temperatures in the room:

- An occupied subzone temperature ( $T_{OC}$ ), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature ( $T_{MX}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the ‘UCSD UFAD Exterior Model Controls’ object.

### 1.13.13.1 Inputs

#### 1.13.13.1.1 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the ‘RoomAirSettings:UnderFloorAirDistributionExterior’ object is needed for each zone that is to be modeled using this method.

#### 1.13.13.1.2 Field: Number of Diffusers

The total number of diffusers in this zone. This field can allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft<sup>2</sup>. The default for this field is Autocalculate.

### 1.13.13.1.3 Field: Power per Plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is *Autocalculate*.

### 1.13.13.1.4 Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m<sup>2</sup>, for variable area diffusers 0.035 m<sup>2</sup>, for horizontal swirl diffusers 0.006 m<sup>2</sup>, and for linear bar grilles 0.03 m<sup>2</sup>. The default is *Autocalculate*.

### 1.13.13.1.5 Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

### 1.13.13.1.6 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

### 1.13.13.1.7 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. The default is 1.1 meters.

### 1.13.13.1.8 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height* and *Room Air Zone Average Temperature Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

### 1.13.13.1.9 Field: Diffuser Type

The choices for this alpha field are **Swirl** | **VariableArea** | **HorizontalSwirl** | **LinearBarGrille** | **Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

### 1.13.13.1.10 Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

### 1.13.13.1.11 Field: Coefficient A

The coefficient A in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.13.1.12 Field: Coefficient B

The coefficient B in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.13.1.13 Field: Coefficient C

The coefficient C in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.13.1.14 Field: Coefficient D

The coefficient D in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.13.13.1.15 Field: Coefficient E

The coefficient E in the formula:  $Kc = A*\Gamma**B + C + D*\Gamma + E*\Gamma**2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

An example input is:

```
RoomAirSettings:UnderFloorAirDistributionExterior,
    SPACE1-1,                      !- Zone Name
    Autocalculate,                  !- Number of Diffusers per Zone
    Autocalculate,                  !- Power per Plume
    Autocalculate,                  !- Design Effective Area of Diffuser {m2}
    Autocalculate,                  !- Diffuser Slot Angle from Vertical {deg}
    ,                                !- Thermostat Height {m}
    ,                                !- Comfort Height {m}
    0.001,                           !- Temperature Difference Threshold for Reporting {deltaC}
    LinearBarGrille,               !- Diffuser Type
    1.7,                            !- Transition Height {m}
    Autocalculate,                  !- Coefficient A
    Autocalculate,                  !- Coefficient B
```

```

Autocalculate,           !- Coefficient C
Autocalculate,           !- Coefficient D
Autocalculate;          !- Coefficient E

```

---

### 1.13.13.2 Outputs

- HVAC,Average,Room Air Zone Mixed Subzone Temperature [C]
- HVAC,Average,Room Air Zone Occupied Subzone Temperature [C]
- HVAC,Average,Room Air Zone Transition Height [m]
- HVAC,Average,Room Air Zone Is Mixed Status []
- HVAC,Average,Room Air Zone Average Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Effective Comfort Air Temperature [C]
- HVAC,Average,Room Air Zone Thermostat Temperature [C]
- HVAC,Average,Room Air Zone Transition Height Gamma Value []
- HVAC,Average,Room Air Zone Plume Heat Transfer Rate [W]
- HVAC,Average,Room Air Zone Window Plume Heat Transfer Rate [W]
- HVAC,Average,Room Air Zone Temperature Stratification Fraction []

#### 1.13.13.2.1 Room Air Zone Mixed Subzone Temperature [C]

The temperature of the upper subzone in degrees C.

#### 1.13.13.2.2 Room Air Zone Occupied Subzone Temperature [C]

The temperature of the lower, occupied subzone in degrees C.

#### 1.13.13.2.3 Room Air Zone Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper subzone..

#### 1.13.13.2.4 Room Air Zone Is Mixed Status []

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD UFE model used). The value 1 means well-mixed; 0 means stratified.

#### 1.13.13.2.5 Room Air Zone Average Temperature Gradient [K/m]

The temperature gradient between the middle of the occupied subzone and the middle of the upper subzone in degrees Kelvin per meter.

#### 1.13.13.2.6 Room Air Zone Effective Comfort Air Temperature [C]

The temperature at the user specified comfort height in degrees C.

#### 1.13.13.2.7 Room Air Zone Thermostat Temperature [C]

The temperature at the height of the thermostat (specified by user input) in degrees C.

### 1.13.13.2.8 Room Air Zone Transition Height Gamma Value []

Value of gamma – a dimensionless “height” used in calculating the transition height. Lower values of gamma indicate increased stratification, higher values less. Generally the values should be between 2 and 30.

### 1.13.13.2.9 Room Air Zone Plume Heat Transfer Rate [W]

The heat in watts driving the plumes in the occupied subzone.

### 1.13.13.2.10 Room Air Zone Window Plume Heat Transfer Rate [W]

The convective heat gain from windows in an UnderFloorAirDistributionExterior zone.

### 1.13.13.2.11 Room Air Zone Temperature Stratification Fraction []

This output, (Phi) is a measure of temperature stratification in the space. It is the difference between the occupied subzone temperature and the supply temperature divided by difference between the return temperature and the supply temperature. Technically it is equal to Kc. As phi approaches 1, the space is fully mixed. As phi approaches 0, the space becomes fully stratified. Expressed as an equation:

$$\frac{T_{occ} - T_{sup}}{T_{ret} - T_{sup}} \quad (1.23)$$

## 1.13.14 RoomAirflowNetwork Model

This model simulates a thermal zone using a network approach by assuming intra-zone nodes connected by user-defined patterns of airflows. The new model also allows users to specify a node to be connected to surfaces to have convective heat transfer between surfaces and the node, portion of internal gains and supply air and return air fractions from zone equipment. The model requires following objects to work together:

- RoomAirSettings:AirflowNetwork
- RoomAir:Node:AirflowNetwork
- RoomAir:Node:AirflowNetwork:AdjacentSurfaceList
- RoomAir:Node:AirflowNetwork:InternalGains
- RoomAir:Node:AirflowNetwork:HVACEquipment
- AirflowNetwork:Intrazone:Node
- AirflowNetwork:Intrazone:Linkage

The first five objects are described below. The last two objects are described in the Airflow Network Model section. This model also requires additional AirflowNetwork:\* objects to form a complete network.

## 1.13.15 RoomAirSettings:AirflowNetwork

This object provides inputs in a thermal zone needed for the RoomAirflowNetwork model. The inputs specify a thermal zone and a list of RoomAir nodes. The object gives a summary of the model configuration in a zone.

### 1.13.15.1 Inputs

#### 1.13.15.1.1 Field: Name

This is a unique character string associated with this instance of the RoomAirSettings:AirflowNetwork object.

#### 1.13.15.1.2 Field: Zone Name

The name of the EnergyPlus thermal zone corresponding to the RoomAir model zone.

#### 1.13.15.1.3 Field: Control Point RoomAir:Node Name

This is the name of a RoomAir:Node:AirflowNetwork object that contains the sensor for zone HVAC controls. The conditions at this node will be used for thermostatic, humidistatic, or comfort based control decisions. The zone node defined in a Zone object is required.

#### 1.13.15.1.4 Field: RoomAir:Node:AirflowNetwork x Name

The name of a RoomAir:Node:AirflowNetwork object defined elsewhere. This node will receive the fraction of internal gains, and HVAC equipment, and a list of surface names exposed to this node with convective heat transfer.

An IDF example input is:

```
RoomAirSettings:AirflowNetwork,
  NORTH_ZONE,          !- Name
  NORTH_ZONE,          !- Zone Name
  RoomAir Schedule,    !- Availability Schedule Name
  NORTH_ZONE,          !- Control Point RoomAir:Node Name
  LeftUpper,           !- RoomAir:Node:AirflowNetwork 1 Name
  CentralUpper,        !- RoomAir:Node:AirflowNetwork 2 Name
  NORTH_ZONE,          !- RoomAir:Node:AirflowNetwork 3 Name
  LeftMiddle,          !- RoomAir:Node:AirflowNetwork 4 Name
  LeftLower,           !- RoomAir:Node:AirflowNetwork 5 Name
  CentralLower;        !- RoomAir:Node:AirflowNetwork 6 Name
```

### 1.13.16 RoomAir:Node:AirflowNetwork

This object is used to define a node in a thermal zone. The input specifies the fraction of zone volume and provides a list of names to define fraction of internal gains, surface connection and HVAC equipment.

### 1.13.16.1 Inputs

#### 1.13.16.1.1 Field: Name

This is a unique character string associated with this instance of the RoomAirSettings:AirflowNetwork object.

#### 1.13.16.1.2 Field: Zone Name

The name of the EnergyPlus thermal zone and is defined in an RoomAirSettings:AirflowNetwork object.

#### 1.13.16.1.3 Field: Fraction of Zone Air Volume

The field specifies a fraction of the overall zone air volume that is assigned to this RoomAir:Node:AirflowNetwork object. The fraction will be used to calculate zone air storage term. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

#### 1.13.16.1.4 Field: RoomAir:Node:AirflowNetwork:AdjacentSurfaceList Name

The field specifies a name to provide a list of connected adjacent surfaces with convective heat transfer between surfaces and this particular node. When a moisture mode is assigned to surfaces, convective moisture transfer will be calculated. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

#### 1.13.16.1.5 Field: RoomAir:Node:AirflowNetwork:InternalGains Name

The field specifies a name to provide a list of internal gain objects and associated fractions assigned to this particular node. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

#### 1.13.16.1.6 Field: RoomAir:Node:AirflowNetwork:HVACEquipment Name

The field specifies a name to provide a list of HVAC equipment, including AirLoop terminals and zone equipment. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

```
RoomAir:Node:AirflowNetwork,
  LeftUpper,          !- Name
  NORTH_ZONE,        !- Zone Name
  0.15,              !- Fraction of Zone Air Volume
  Surface_18_T_List, !- RoomAir:Node:AirflowNetwork:AdjacentSurfaceList Name
  LeftUpper_Gain,    !- RoomAir:Node:AirflowNetwork:InternalGains Name
  LeftUpper_HVAC;    !- RoomAir:Node:AirflowNetwork:HVACEquipment Name
```

### 1.13.17 RoomAir:Node:AirflowNetwork:AdjacentSurfaceList

This object is used to provide a list of connected adjacent surfaces with convective heat transfer between surfaces and this particular node. When a moisture mode is assigned to surfaces, convective moisture transfer will be calculated. It should be pointed out that a fraction of a surface exposed to this particular node is not allowed.

#### 1.13.17.0.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:AdjacentSurfaceList object.

#### 1.13.17.0.2 Field: Surface <#> Name

The field specifies a surface name. This object is extensible, so additional fields of this type can be added to the end of this object.

```
RoomAir:Node:AirflowNetwork:AdjacentSurfaceList,
  Surface_18_T_List, !- Name
  Surface_18_T;     !- Surface 1 Name
```

### 1.13.18 RoomAir:Node:AirflowNetwork:InternalGains

This object is used to define a list of internal gains in the same zone and associated fraction assigned to this particular node.

### 1.13.18.1 Inputs

#### 1.13.18.1.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:-InternalGains object.

#### 1.13.18.1.2 Field: Internal Gain Object <#> Type

The field specifies an internal gain object type based on the list in EnergyPlus.

#### 1.13.18.1.3 Field: Internal Gain Object <#> Name

The field specifies an internal gain object name based on the list in EnergyPlus.

#### 1.13.18.1.4 Field: Fraction of Gains to Node <#>

The field specifies a fraction of the particular internal gain object assigned to this node.

This object is extensible, so additional groups of these last three fields can be added to the end of this object.

```
RoomAir:Node:AirflowNetwork:InternalGains,
  CentralUpper_Gain,      !- Name
  People,                 !- Internal Gain Object 1 Type
  NORTH_ZONE People,      !- Internal Gain Object 1 Name
  0.15,                   !- Fraction of Gains to Node 1
  Lights,                 !- Internal Gain Object 2 Type
  NORTH_ZONE Lights,      !- Internal Gain Object 2 Name
  0.15,                   !- Fraction of Gains to Node 2
  ElectricEquipment,     !- Internal Gain Object 3 Type
  NORTH_ZONE Equip,       !- Internal Gain Object 3 Name
  0.15;                  !- Fraction of Gains to Node 3
```

---

### 1.13.19 RoomAir:Node:AirflowNetwork:HVACEquipment

This object is used to define a list of HVAC equipment objects in the same zone and associated fractions assigned to this particular node.

#### 1.13.19.1 Inputs

##### 1.13.19.1.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:-HVACEquipment object.

##### 1.13.19.1.2 Field: ZoneHVAC or Air Terminal Equipment Object Type <#>

The field specifies an object type of ZoneHVAC equipment or terminal type based on the list in the Energy+.idd.

##### 1.13.19.1.3 Field: ZoneHVAC or Air Terminal Equipment Object Name <#>

The field specifies the object name based on the object type defined in the previous field.

##### 1.13.19.1.4 Field: Fraction of Output or Supply Air from HVAC Equipment <#>

The field specifies a fraction of supply air from the particular equipment to this node.

### 1.13.19.1.5 Field: Fraction of Input or Return Air from HVAC Equipment <#>

The field specifies a fraction of return air from the particular equipment to this node.

This object is extensible, so additional groups fields of these last four fields can be added to the end of this object.

```
RoomAir:Node:AirflowNetwork:HVACEquipment,
  CentralUpper_HVAC,           !- Name
  ZoneHVAC:PackagedTerminalAirConditioner, !- ZoneHVAC or Air Terminal Equipment Object Type 1
  NORTH_ZONE_PTAC,            !- ZoneHVAC or Air Terminal Equipment Object Name 1
  0.14,                      !- Fraction of Output or Supply Air from HVAC Equipment 1
  0.14;                      !- Fraction of Input or Return Air to HVAC Equipment 1
```

### 1.13.19.2 Outputs

Each room air model sets up outputs specific to that model. The effect of room air modeling is usually to adjust the adjacent air temperature along the inside surface of heat transfer surfaces. The output report “Surface Int Adjacent Air Temperature [C]” is provided for this and described under Surface Outputs.

#### 1.13.19.2.1 Zone Predicted Sensible Load Room Air Correction Factor

This output variable provides the value of the correction factor applied to the predicted zone loads. Predicted zone load to setpoint is (usually) used to control HVAC air systems and the presence of a room air model has an impact on the loads. The predicted loads are multiplied by the factor in this output variable. The value is always 1.0 when there is no Room Air model. When there is a Room Air model, this output shows how that model is increasing or decreasing overall zone loads experienced by the air system.

### 1.13.19.3 Outputs

- HVAC,Average,RoomAirflowNetwork Node Temperature [C]
- HVAC,Average,RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,RoomAirflowNetwork Node Relative Humidity [%]
- HVAC,Average,RoomAirflowNetwork Node SumIntSensibleGain [W]
- HVAC,Average,RoomAirflowNetwork Node SumIntLatentGain [W]
- HVAC,Average,RoomAirflowNetwork Node NonAirSystemResponse [W]
- HVAC,Average,RoomAirflowNetwork Node SysDepZoneLoadsLagged [W]
- HVAC,Average,RoomAirflowNetwork Node HVAC Supply Fraction []
- HVAC,Average,RoomAirflowNetwork Node HVAC Return Fraction []

#### 1.13.19.3.1 RoomAirflowNetwork Node Temperature [C]

The temperature at a Room Air Node in a zone in degrees C.

#### 1.13.19.3.2 HVAC,Average,RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]

The humidity ratio at a Room Air Node in a zone in kgWater/kgDryAir.

**1.13.19.3.3 RoomAirflowNetwork Node Relative Humidity [%]**

The relative humidity ratio at a Room Air Node in a zone in percent.

**1.13.19.3.4 HVAC,Average,RoomAirflowNetwork Node SumIntSensibleGain [W]**

A sum of internal sensible gains assigned to a Room Air node in a zone.

**1.13.19.3.5 HVAC,Average,RoomAirflowNetwork Node SumIntLatentGain [W]**

A sum of internal latent gains assigned to a Room Air node in a zone.

**1.13.19.3.6 HVAC,Average,RoomAirflowNetwork Node NonAirSystemResponse [W]**

A sum of system convective gains, collected via NonAirSystemResponse, and assigned to a Room Air node in a zone.

**1.13.19.3.7 HVAC,Average,RoomAirflowNetwork Node SysDepZoneLoadsLagged [W]**

A sum of SysDepZoneLoads saved to be added to zone heat balance at the next HVAC time step. A typical system is a zone dehumidifier.

## **1.14 Group – Internal Gains (People, Lights, Other internal zone equipment)**

Not all the influence for energy consumption in the building is due to envelope and ambient conditions. This group of objects describes other internal gains that may come into play (**People**, **Lights**, Various Equipment Types).

### **1.14.1 Specifying Applicable Zone(s) or Space(s)**

Each internal gains object has a field for “**Zone** or **ZoneList** or **Space** or **SpaceList Name**”. All internal gains are modeled at the Space level, so each internal gain input object may be expanded to multiple instances of that gain according to the following rules with names constructed using the <Object Name>, <Zone Name>, or <Space Name>. If the resulting concatenated name is greater than 100 characters a warning will be shown and it will be truncated. If the resulting name duplicates another such concatenated name, there will be a severe error and terminate the run. The concatenated name is used when referring to specific instances of internal gains for **Output:Variables**, **Energy Management System (EMS)** controls, and **Demand Limiting Controls**.

**Space Name** will result in one instance of the internal gain, named <Object Name>. The full magnitude of the gain will be applied to the Space using the design level, space floor area, or space occupancy as appropriate.

**SpaceList Name** will result in one instance of the internal gain for each Space in the SpaceList, named <Space Name> <Object Name>. The full magnitude of the gain will be applied to each Space in the SpaceList using the design level, space floor area, or space occupancy as appropriate.

**Zone Name** will result in one instance of the internal gain for each Space in the Zone. If there is only one Space in the Zone, then the single instance will be named <Object Name>. If there is more than one Space in the Zone, then each instance will be named <Space Name> <Object Name>. The full

magnitude of the gain will be split between the Spaces in the Zone apportioned by the Space floor area or occupancy depending on the input method.

**ZoneList Name** will result in one instance of the internal gain for each Space in each Zone in the ZoneList.

Each instance will be named <Space Name> <Object Name>. The full magnitude of the gain will be applied to each Zone in the ZoneList then split between the Spaces in each Zone apportioned by the Space floor area or occupancy depending on the input method.

One exception to this is **ElectricEquipment:ITE:AirCooled** which only allows Zone or Space Name. If a Zone Name is specified which contains more than one Space, the same rules apply.

As an example, assume that Zone 1 contains Space 1A and Space 1B, and Zone 2 contains only Space 2 (objects are abbreviated for clarity):

```

Space,
Space 1A, !- Name
Zone 1,    !- Zone Name
75.0,     !- Floor Area

Space,
Space 1B, !- Name
Zone 1;   !- Zone Name
25.0,    !- Floor Area

Space,
Space 2,  !- Name
Zone 2,   !- Zone Name

SpaceList,
All Spaces, !- Name
Space 1A,   !- Space 1 Name
Space 1B,   !- Space 2 Name
Space 2,    !- Space 3 Name

People,
Office People, !- Name
Zone 1,      !- Zone or ZoneList or Space or SpaceList Name
100.0,     !- Number of People

People,
Lunchroom People, !- Name
Zone 2,      !- Zone or ZoneList or Space or SpaceList Name
50.0,      !- Number of People

People,
Cleaning Crew, !- Name
All Spaces, !- Zone or ZoneList or Space or SpaceList Name
2.0,       !- Number of People

Resulting instances of People:

Space 1A Office People, 75 people. (concatenated name, apportioned by space floor area)
Space 1B Office People, 25 people. (concatenated name, apportioned by space floor area)
Lunchroom People, 50 people.      (simple object name for a single space)
Space 1A Cleaning Crew, 2 people. (full load applied to each space in SpaceList)
Space 1B Cleaning Crew, 2 people.
Space 2 Cleaning Crew, 2 people.

```

## 1.14.2 People

The people statement is used to model the occupant's effect on the space conditions. The following definition addresses the basic affects as well as providing information that can be used to report the thermal comfort of a group of occupants. The Fanger, Pierce Two-Node, Kansas State University Two-Node, ASHRAE Standard 55 Elevated Air Cooling Effect model, and ASHRAE Standard 55 Ankle Draft

Risk thermal comfort models are available in EnergyPlus. A user may select any of these models for each People statement by simply adding the appropriate choice keyword after the air velocity schedule name. Thermal comfort calculations will only be made for people statements that include specific requests for these thermal comfort models. This object also requires input of carbon dioxide generation rate based on people activity level for zone carbon dioxide simulations.

### 1.14.2.1 Inputs

#### 1.14.2.1.1 Field: Name

The name of the People object. Must be unique across all People objects.

#### 1.14.2.1.2 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this People object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the people/area and area/person options of the Number of People Calculation Method to place a varying number of people at the same density in each zone or space. The names of the actual people objects may be concatenated as <Space Name> <People Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

#### 1.14.2.1.3 Field: Number of People Schedule Name

This field is the name of the schedule (ref: Schedules) that modifies the number of people parameter (see Number of People Calculation Method and related fields). The schedule values can be any positive number. The actual number of people in a zone as defined by this statement is the product of the number of people field and the value of the schedule specified by name in this field.

#### 1.14.2.1.4 Field: Number of People Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal number of occupants (people) in the Zone. The key/choices are:

- People

With this choice, the method used will be a straight insertion of the number of occupants (people). (The Number of People field should be filled.)

- People/Area

With this choice, the method used will be a factor per floor area of the zone. (The People per Zone Floor Area field should be filled).

- Area/Person

With this choice, the method used will be a factor of floor area per person. (The Zone Floor Area per Person field should be filled).

#### 1.14.2.1.5 Field: Number of People

This field is used to represent the maximum number of people in a zone that is then multiplied by a schedule fraction (see schedule field). In EnergyPlus, this is slightly more flexible in that the number of people could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the number of people field is constant for all simulation environments.

#### 1.14.2.1.6 Field: People per Zone Floor Area

This factor ( $\text{person}/\text{m}^2$ ) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be “people/area”.

#### 1.14.2.1.7 Field: Zone Floor Area per Person

This factor ( $\text{m}^2/\text{person}$ ) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be “area/person”.

#### 1.14.2.1.8 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by people in a zone. The number specified in this field will be multiplied by the total sensible energy emitted by people to give the amount of long wavelength radiation gain from human beings in a zone. The remainder of the sensible load is assumed to be convective heat gain. Note that latent gains from people are not included in either the radiant or convective heat gains. See the Engineering Reference document for more details. Default value is 0.30.

#### 1.14.2.1.9 Field: Sensible Heat Fraction

The user can use this field to specify a fixed sensible fraction for the heat gain due to this PEOPLE object. Normally the program calculates the sensible/latent split; this field gives the user control over this split. This field is autocalculated: if the field is blank or **autocalculate**, the program will calculate the sensible/latent split; if a value is entered, it will be used as the sensible fraction of the current total heat gain.

#### 1.14.2.1.10 Field: Activity Level Schedule Name

This field is the name of the schedule that determines the amount of heat gain per person in the zone under design conditions. This heat gain impacts the basic zone heat balance as well as the modeling of thermal comfort. This value is modified somewhat based on a correlation to account for variations in space temperature. The schedule values may be any positive number and the units for this parameter is Watts per person. This schedule represents the total heat gain per person including convective, radiant, and latent. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Then, the sensible portion is divided into radiant and convective portions using the value specified for Fraction Radiant (above). See the Engineering Reference document for more details.

Values for activity level can range anywhere from approximately 100-150 Watts per person for most office activities up to over 900 Watts per person for strenuous physical activities such as competitive wrestling. The following table (Table 1.25) is based on Table 1.10 from the 2005 ASHRAE Handbook of Fundamentals, page 8.6. In addition to the information from the ASHRAE HOF, there is an added column of values in W/Person such as necessary for the activity level schedule values. This column uses the standard adult body surface area of  $1.8 \text{ m}^2$  to multiply the activity levels in  $\text{W}/\text{m}^2$  that are used in the table. Warnings are produced when the activity level schedule values fall outside normal ranges. Having too low or too high values can also skew thermal comfort reporting values.

#### 1.14.2.1.11 Field: Carbon Dioxide Generation Rate

This numeric input field specifies carbon dioxide generation rate per person with units of  $\text{m}^3/\text{s-W}$ . The total carbon dioxide generation rate from this object is:

Number of People \* People Schedule \* People Activity \* Carbon Dioxide Generation Rate. The default value is 3.82E-8 m<sup>3</sup>/s-W (obtained from ASHRAE Standard 62.1-2007 value at 0.0084 cfm/met/person over the general adult population). The maximum value can be 10 times the default value.

#### 1.14.2.1.12 Field: Enable ASHRAE 55 comfort warnings

This field accepts either “Yes” or “No” as values. When “Yes” is specified, warnings are generated when the space conditions are outside of the ASHRAE 55 comfort range as discussed in the sections that follow titled “Simplified ASHRAE 55-2004 Graph Related Outputs” and “Simplified ASHRAE 55 Warnings.” The default is not to provide these warnings so if you want to know if your space is outside this comfort range you must set this field to Yes.

Table 1.25: Metabolic Rates for Various Activities

Activity	Activity Level Schedule Value (W/Person)	Activity Level (W/m <sup>2</sup> )	met*
<i>Resting</i>			
Sleeping	72	40	0.7
Reclining	81	45	0.8
Seated, quiet	108	60	1
Standing, relaxed	126	70	1.2
<i>Walking (on level surface)</i>			
3.2 km/h (0.9 m/s)	207	115	2
4.3 km/h (1.2 m/s)	270	150	2.6
6.4 km/h (1.8 m/s)	396	220	3.8
<i>Office Activities</i>			
Reading, seated	99	55	1
Writing	108	60	1
Typing	117	65	1.1
Filing, seated	126	70	1.2
Filing, standing	144	80	1.4
Walking about	180	100	1.7
Lifting/packing	216	120	2.1
<i>Miscellaneous Occupational Activities</i>			
Cooking	171 to 207	95 to 115	1.6 to 2.0
Housecleaning	207 to 360	115 to 200	2.0 to 3.4
Seated, heavy limb movement	234	130	2.2
Machine work	189	105	1.8
sawing (table saw)	207 to 252	115 to 140	2.0 to 2.4
light (electrical industry)	423	235	4
Handling 50 kg bags	423	235	4

Table 1.25: Metabolic Rates for Various Activities

Activity	Activity Level Schedule Value (W/Person)	Activity Level (W/m <sup>2</sup> )	met*
Pick and shovel work	423 to 504	235 to 280	4.0 to 4.8
<i>Miscellaneous</i>	<i>Leisure</i>		
<i>Activities</i>			
Dancing, social	252 to 459	140 to 255	2.4 to 4.4
Calisthenics/exercise	315 to 423	175 to 235	3.0 to 4.0
Tennis, singles	378 to 486	210 to 270	3.6 to 4.0
Basketball, competitive	522 to 792	290 to 440	5.0 to 7.6
Wrestling, competitive	738 to 909	410 to 505	7.0 to 8.7

\*Note that one met = 58.1 W/m<sup>2</sup>

#### 1.14.2.1.13 Field: Mean Radiant Temperature Calculation Type

This field specifies the type of Mean Radiant Temperature (MRT) calculation the user wishes to use for the thermal comfort model. At the present time, there are three options for MRT calculation type: zone averaged, surface weighted, and a list of angle factors. The default calculation is “ZoneAveraged” and is used if field is left blank. In the zone averaged MRT calculation, the MRT used for the thermal comfort calculations is for an “average” point in the zone. MRT is calculated based on an area-emissivity weighted average of all of the surfaces in the zone. In cases where the emissivity of all of the surfaces are sufficiently small (near zero), the mean radiant temperature will be set to the mean air temperature of the space to avoid divide by zero errors. The other MRT calculation type is “SurfaceWeighted”. The goal of this calculation type is to estimate a person in the space close to a particular surface without having to define exact view factors for all of the surfaces and the location of the person in the space. The MRT used in the thermal comfort calculations when the “surface weighted” calculation type is selected is actually the average of the temperature of the surface to which the person is closest (defined by the next field “Surface Name”) and the zone averaged MRT (defined above). The surface temperature alone is not used because in theory the maximum view factor from a person to any flat surface is roughly 0.5. In the “surfaceweighted” calculation, the surface in question actually gets slightly more weighting than 50% since the surface selected is still a part of the zone average MRT calculation. Again, this simplification was made to avoid the specification of view factors and the exact location of the person.

A third option is to use “AngleFactor”. This option allows for more explicit positioning of the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The [ComfortViewFactorAngles](#) object (see next object description) is intended to give the user this opportunity.

#### 1.14.2.1.14 Field: Surface Name/Angle Factor List Name

This field is only valid when the user selects “SurfaceWeighted” or “AngleFactor” for the MRT calculation type (see the previous input field description). In the case of “SurfaceWeighted”, the field is the name of a surface within the zone the people are residing. This surface will be used in the MRT calculation as defined above to come up with a more representative MRT for a person near a particular surface. The MRT used for thermal comfort calculations using the “SurfaceWeighted” MRT calculation method is the average of the temperature of the surface specified in this field and the “zone averaged”

MRT (see the Mean Radiant Temperature calculation type field above). In the case of “AngleFactor”, the field is the name of a **ComfortViewFactorAngles** input object defined elsewhere. This field is required when the previous field is set to “SurfaceWeighted” or “AngleFactor” and is set to run one of the following thermal comfort models: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55.

#### 1.14.2.1.15 Field: Work Efficiency Schedule Name

This field is the name of the schedule that determines the efficiency of energy usage within the human body that will be used for thermal comfort calculations. Note that all energy produced by the body is assumed to be converted to heat for the zone heat balance calculation. A value of zero corresponds to all of the energy produced in the body being converted to heat. A value of unity corresponds to all of the energy produced in the body being converted to mechanical energy. The values for this parameter defined in the schedule must be between 0.0 and 1.0. Any value greater than zero will result in a reduction of heat that impacts the thermal comfort energy balance of a person within the space, resulting in PMV results appearing lower than expected. Ensure that if this value is non-zero, the base activity level is chosen to ensure that the net activity converted to heat and zone conditions are sufficient to maintain thermal comfort. This field is required to run one of the following thermal comfort models: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. If a schedule is listed here but no thermal comfort model is selected, then a warning message will be produced and this schedule will be listed as unused in the error file.

#### 1.14.2.1.16 Field: Clothing Insulation Calculation Method

This field is a key/choice field that tells which of the next two fields are filled and is descriptive of the method for calculating the clothing insulation value of occupants (people) in the Zone. The key/choices are:

- ClothingInsulationSchedule

With this choice, the method used will be a straight insertion of the scheduled clothing insulation values of occupants (people). (The Clothing Insulation Schedule Name field should be filled.)

- DynamicClothingModelASHRAE55

With this choice, the method used will be the dynamic predictive clothing insulation model developed by Schiavon and Lee (2013) based on 6,333 selected observations taken from ASHRAE RP-884 and RP-921 databases. It varies the clothing insulation as a function of outdoor air temperature measured at 6am as illustrated below.

- CalculationMethodSchedule

With this choice, the method used can be either the ClothingInsulationSchedule or the DynamicClothingModelASHRAE55, depending on a schedule (to be entered as the next field) that determines which method to use in different time of a day. When this option is chosen, the next field “Clothing Insulation Calculation Method Schedule Name” is a required input.

#### 1.14.2.1.17 Field: Clothing Insulation Calculation Method Schedule Name

This field specifies which clothing insulation method (ClothingInsulationSchedule or DynamicClothingModelASHRAE55) to use at a particular time of the day. A schedule value of 1 means the ClothingInsulationSchedule method, and 2 means the DynamicClothingModelASHRAE55 method. This field is only required when the “Clothing Insulation Calculation Method” field is set to **CalculationMethodSchedule**. If this field is left blank, the specified clothing insulation calculation method will be used and not changed during the simulation.

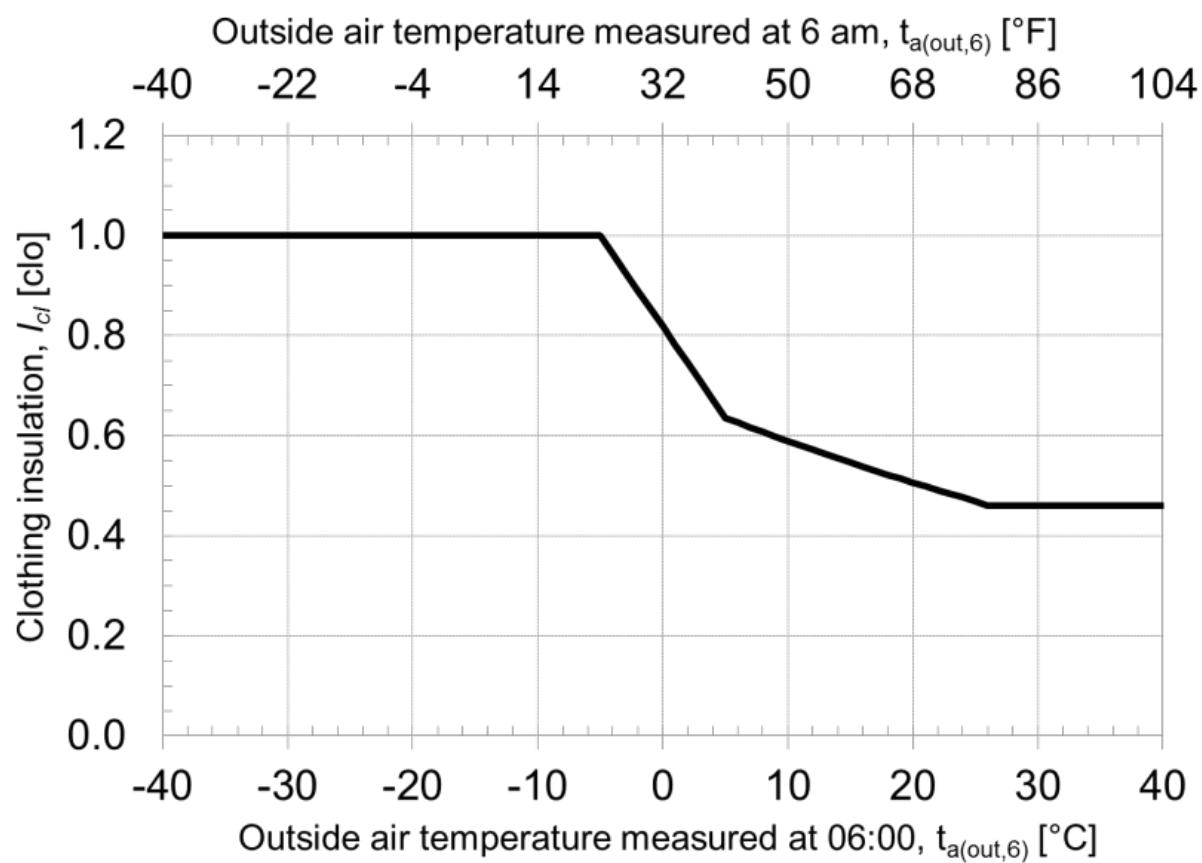

Figure 1.69: Graphical representation of the dynamic predictive clothing insulation model

#### 1.14.2.1.18 Field: Clothing Insulation Schedule Name

This field is the name of the schedule that defines the amount of clothing being worn by a typical zone occupant during various times in the simulation period. The choice from the Clothing Insulation Calculation Method field should be “**ClothingInsulationSchedule**”. This parameter must be a positive real number and has units of Clo. Typical values for Clo can be seen in the ASHRAE 2009 HOF Table 7, page 9.8 (for clothing ensembles) and Table 1.14, page 9.9 (for garment values) ) or [www.cbe.berkeley.edu/comforttool/](http://www.cbe.berkeley.edu/comforttool/). This field is required to run one of the following thermal comfort models: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. If a schedule is listed here but no thermal comfort model is selected, then a warning message will be produced and this schedule will be listed as unused in the error file.

#### 1.14.2.1.19 Field: Air Velocity Schedule Name

This field is the name of the schedule that approximates the amount of air movement in the space as a function of time throughout the simulation period. The user has control over this parameter through the schedule that requires the individual numbers in the schedule to be positive real numbers having units of meters per second. This field is required to run one of the following thermal comfort models: Fanger, Pierce, KSU, CoolingEffectASH55 or AnkleDraftASH55. If a schedule is listed here but no thermal comfort model is selected, then a warning message will be produced and this schedule will be listed as unused in the error file.

#### 1.14.2.1.20 Field: Thermal Comfort Model Type (up to 7 allowed)

The final one to five fields are optional and are intended to trigger various thermal comfort models within EnergyPlus. By entering the keywords Fanger, Pierce, KSU, AdaptiveASH55, AdaptiveCEN15251, CoolingEffectASH55, and AnkleDraftASH55, the user can request the Fanger, Pierce Two-Node, Kansas State UniversityTwo-Node, the adaptive comfort models of the ASHRAE Standard 55 and CEN Standard 15251, ASHRAE Standard 55 Elevated Air Cooling Effect model, and ASHRAE Standard 55 Ankle Draft Risk model results for this particular people statement. Detailed descriptions and requirements of the seven models as listed below.

**Fanger** Fanger’s Comfort model is applied to calculate related thermal comfort metrics. Fanger Model PMV, PPD, and Clothing Surface Temperature are calculated and reported as each time step. Apart from existing required fields in People object, extra fields required for this model include Surface Name/Angle Factor List Name, Work Efficiency Schedule Name, Clothing Insulation Schedule Name, and Air Velocity Schedule Name.

**Pierce** The Pierce Two-Node model is applied to calculate related thermal comfort metrics. Pierce Model Effective Temperature PMV, Standard Effective Temperature PMV, Discomfort Index, Thermal Sensation Index, and Standard Effective Temperature are calculated and reported as each time step. Apart from existing required fields in People object, extra fields required for this model include Surface Name/Angle Factor List Name, Work Efficiency Schedule Name, Clothing Insulation Schedule Name, and Air Velocity Schedule Name.

**KSU** The KSU Two-Node Model is applied to calculate related thermal comfort metrics. KSU Model Thermal Sensation Vote is calculated and reported as each time step. Note that the KSU model is computationally intensive and may noticeably increase the execution time of the simulation. Apart from existing required fields in People object, extra fields required for this model include Surface Name/Angle Factor List Name, Work Efficiency Schedule Name, Clothing Insulation Schedule Name, and Air Velocity Schedule Name.

**AdaptiveASH55** Adaptive Comfort Model Based on ASHRAE Standard 55-2010 is applied to calculate related thermal comfort metrics. ASHRAE 55 Adaptive Model 90% Acceptability Status, 80% Acceptability Status, Running Average Outdoor Air Temperature, and the Adaptive Model Temperature are calculated and reported as each time step. AdaptiveASH55 is only applicable when the running average outdoor air temperature for the past 7 days is between 10.0 and 33.5C.

**AdaptiveCEN15251** Adaptive Comfort Model Based on European Standard EN15251-2007 is applied to calculate related thermal comfort metrics. CEN 15251 Adaptive Model Category I/II/II Status, Running Average Outdoor Air Temperature, and the Adaptive Model Temperature are calculated and reported as each time step. AdaptiveCEN15251 is only applicable when the running average outdoor air temperature for the past 30 days is between 10.0 and 30.0C.

**CoolingEffectASH55** ASHRAE 55-2017 Elevated Air Speed Cooling Effect Model is applied to calculate related thermal comfort metrics. Elevated Air Speed Cooling Effect, Cooling Effect Adjusted PMV, and Cooling Effect Adjusted PPD are calculated and reported as each time step. Apart from existing required fields in People object, extra fields required for this model include Surface Name/Angle Factor List Name, Work Efficiency Schedule Name, Clothing Insulation Schedule Name, and Air Velocity Schedule Name.

**AnkleDraftASH55** ASHRAE 55-2017 Ankle Draft Risk Model is applied to calculate related thermal comfort metrics. Zone Thermal Comfort ASHRAE 55 Ankle Draft PPD is calculated and reported as each time step. Apart from existing required fields in People object, extra fields required for this model include Surface Name/Angle Factor List Name, Work Efficiency Schedule Name, Clothing Insulation Schedule Name, Air Velocity Schedule Name, and Ankle Level Air Velocity Schedule Name. Ankle draft PPD calculations are only applicable for relative air velocity is below 0.2 m/s, and the subject's metabolic rate and clothing level should be kept below 1.3 met and 0.7 clo. PPD at ankle draft will be set to -1.0 if these conditions are not met.

For descriptions of the thermal comfort calculations, see the Engineering Reference document.

Note that since up to seven models may be specified, the user may opt to have EnergyPlus calculate the thermal comfort for people identified with this people statement using all seven models if desired.

#### 1.14.2.1.21 Field: Ankle Level Air Velocity Schedule Name

This field is the name of the schedule that approximates the amount of air movement at the occupants' ankle level (0.1 m above floor level) as a function of time throughout the simulation period. The user has control over this parameter through the schedule that requires the individual numbers in the schedule to be positive real numbers having units of meters per second. This field is required to run the AnkleDraftASH55 thermal comfort model. If a schedule is listed here but no thermal comfort model is selected, then a warning message will be produced and this schedule will be listed as unused in the error file.

The following IDF example allows for a maximum of 31 people with scheduled occupancy of "Office Occupancy", 60% radiant using an Activity Schedule of "Activity Sch". The example allows for thermal comfort reporting.

```
People,
  Kitchen_ZN_1_FLR_1,      !- Name
  Kitchen_ZN_1_FLR_1,      !- Zone or ZoneList or Space or SpaceList Name
  BLDG_OCC_SCH,            !- Number of People Schedule Name
  People,                  !- Number of People Calculation Method
  25.2000,,,               !- Number of People, People per Zone Floor Area, Zone Floor Area per Person
  0.3000,                  !- Fraction Radiant
  AUTOCALCULATE,           !- Sensible Heat Fraction
  ACTIVITY_SCH,             !- Activity Level Schedule Name
  3.82E-8,                 !- Carbon Dioxide Generation Rate {m3/s-W}
```

```
No,           !- Enable ASHRAE 55 Comfort Warnings

### 1.14.2.2 Outputs

People objects have output variables for individual objects and for space and zone totals.

People specific outputs include:

- Zone,Average,People Occupant Count []
- Zone,Sum,People Radiant Heating Energy [J]
- Zone,Average,People Radiant Heating Rate [W]
- Zone,Sum,People Convective Heating Energy [J]
- Zone,Average,People Convective Heating Rate [W]
- Zone,Sum,People Sensible Heating Energy [J]
- Zone,Average,People Sensible Heating Rate [W]
- Zone,Sum,People Latent Gain Energy [J]
- Zone,Average,People Latent Gain Rate [W]
- Zone,Sum,People Total Heating Energy [J]
- Zone,Average,People Total Heating Rate [W]
- Zone,Average,Space People Occupant Count []
- Zone,Sum,Space People Radiant Heating Energy [J]
- Zone,Average,Space People Radiant Heating Rate [W]
- Zone,Sum,Space People Convective Heating Energy [J]
- Zone,Average,Space People Convective Heating Rate [W]
- Zone,Sum,Space People Sensible Heating Energy [J]
- Zone,Average,Space People Sensible Heating Rate [W]
- Zone,Sum,Space People Latent Gain Energy [J]
- Zone,Average,Space People Latent Gain Rate [W]
- Zone,Sum,Space People Total Heating Energy [J]
- Zone,Average,Space People Total Heating Rate [W]
- Zone,Average,Zone People Occupant Count []
- Zone,Sum,Zone People Radiant Heating Energy [J]
- Zone,Average,Zone People Radiant Heating Rate [W]
- Zone,Sum,Zone People Convective Heating Energy [J]
- Zone,Average,Zone People Convective Heating Rate [W]
- Zone,Sum,Zone People Sensible Heating Energy [J]
- Zone,Average,Zone People Sensible Heating Rate [W]

- Zone,Sum,Zone People Latent Gain Energy [J]
- Zone,Average,Zone People Latent Gain Rate [W]
- Zone,Sum,Zone People Total Heating Energy [J]
- Zone,Average,Zone People Total Heating Rate [W]
- Zone,Average,People Air Temperature [C]
- Zone,Average,People Air Relative Humidity [%]
- Zone,Average,Zone Thermal Comfort Mean Radiant Temperature [C]
- Zone,Average,Zone Thermal Comfort Operative Temperature [C]
- Zone,Average,Zone Thermal Comfort Fanger Model PMV []
- Zone,Average,Zone Thermal Comfort Fanger Model PPD [%]
- Zone,Average,Zone Thermal Comfort Clothing Surface Temperature [C]
- Zone,Average,Zone Thermal Comfort Pierce Model Effective Temperature PMV []
- Zone,Average,Zone Thermal Comfort Pierce Model Standard Effective Temperature PMV []
- Zone,Average,Zone Thermal Comfort Pierce Model Discomfort Index []
- Zone,Average,Zone Thermal Comfort Pierce Model Thermal Sensation Index []
- Zone,Average,Zone Thermal Comfort Pierce Model Standard Effective Temperature [C]
- Zone,Average,Zone Thermal Comfort KSU Model Thermal Sensation Index []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model 80% Acceptability Status []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model 90% Acceptability Status []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model Running Average Outdoor Air Temperature [C]
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model Temperature [C]
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category I Status []
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category II Status []
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category III Status
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Running Average Outdoor Air Temperature [C]
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Temperature [C]
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect [C]
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect Adjusted PMV []

- Zone,Average,Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect Adjusted PPD []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Ankle Draft PPD []

It should be noted that if a user is trying to output the Standard Effective Temperature (SET) that the Pierce two-node model must be selected. This variable is calculated as part of the Pierce model and can be seen in the output by requesting Zone Thermal Comfort Pierce Model Standard Effective Temperature.

#### 1.14.2.2.1 People Occupant Count []

This field is the number of people for this PEOPLE object during the timestep in question.

#### 1.14.2.2.2 People Radiant Heating Rate [W]

#### 1.14.2.2.3 People Radiant Heating Energy [J]

These output variables are the amount of radiant heat gain for this People object in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

#### 1.14.2.2.4 People Convective Heating Rate [W]

#### 1.14.2.2.5 People Convective Heating Energy [J]

These output variables are the amount of convective heat gain for this People object in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the zone air heat balance directly.

#### 1.14.2.2.6 People Latent Gain Rate [W]

#### 1.14.2.2.7 People Latent Gain Energy [J]

These output variables are the amount of latent heat gain for this People object in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

#### 1.14.2.2.8 People Sensible Heating Rate [W]

#### 1.14.2.2.9 People Sensible Heating Energy [J]

These output variables are the amount of sensible heat gain for this People object in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

#### 1.14.2.2.10 People Total Heating Rate [W]

#### 1.14.2.2.11 People Total Heating Energy [J]

These output variables are the total amount of heat gain for this People object in Watts (for rate) or Joules. This is derived from the activity level times the number of occupants.

#### 1.14.2.2.12 People Air Temperature [C]

This output variable represents the zone air temperature based on the Fanger thermal comfort model. If there is a ZoneControl:Thermostat:ThermalComfort object specified and the thermal zone is occupied, then the value of “People Air Temperature” is determined based on the thermal comfort that satisfies the thermal comfort setpoint PMV value specified; otherwise, it is set to average zone air temperature.

#### 1.14.2.2.13 People Air Relative Humidity [%]

This output variable represents the zone air relative humidity based on the Fanger thermal comfort model. If there is a ZoneControl:Thermostat:ThermalComfort object specified and the thermal zone is occupied, then the value of “People Air Relative Humidity” is determined from the mean zone air temperature and zone air humidity ratio that satisfies the thermal comfort setpoint PMV value specified; otherwise, it is calculated from the zone air temperature and humidity ratio averaged over the time step.

#### 1.14.2.2.14 Space or Zone People Occupant Count []

This field is the total number of people within the space or zone during the timestep in question.

#### 1.14.2.2.15 Space or Zone People Radiant Heating Rate [W]

#### 1.14.2.2.16 Space or Zone People Radiant Heating Energy [J]

These output variables are the amount of radiant heat gain from people within the space or zone in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the space or zone and the “Fraction Radiant” specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

#### 1.14.2.2.17 Space or Zone People Convective Heating Rate [W]

#### 1.14.2.2.18 Space or Zone People Convective Heating Energy [J]

These output variables are the amount of convective heat gain from people within the space or zone in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the space or zone and the “Fraction Radiant” specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the space or zone air heat balance directly.

#### 1.14.2.2.19 Space or Zone People Latent Gain Rate [W]

#### 1.14.2.2.20 Space or Zone People Latent Gain Energy [J]

These output variables are the amount of latent heat gain from people within the space or zone in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

#### 1.14.2.2.21 Space or Zone People Sensible Heating Rate [W]

**1.14.2.2.22 Space or Zone People Sensible Heating Energy [J]**

These output variables are the amount of sensible heat gain from people within the space or zone in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

**1.14.2.2.23 Space or Zone People Total Heating Rate [W]****1.14.2.2.24 Space or Zone People Total Heating Energy [J]**

These output variables are the total amount of heat gain from people within the space or zone in Watts (for rate) or Joules. Derived from the activity level times the number of occupants, this is summed for each people object within a zone.

**1.14.2.2.25 Zone Thermal Comfort Mean Radiant Temperature [C]**

This output variable is the mean radiant temperature used in the thermal comfort calculations. This value is computed according to the “MRT Calculation Type” specified in the PEOPLE object. If a high temperature radiant system is present in the zone, this value will be adjusted according to the current heater operation and the “Fraction of radiant energy incident on people” specified in the HIGH TEMP RADIANT SYSTEM object.

**1.14.2.2.26 Zone Thermal Comfort Operative Temperature [C]**

This output variable is the operative temperature as defined by the thermal comfort operations. Specifically, it is the average of the thermal comfort mean radiant temperature and the zone air temperature.

Note for all Thermal Comfort reporting: Though the published values for thermal comfort “vote” have a discrete scale (e.g. -3 to +3 or -4 to +4), the calculations in EnergyPlus are carried out on a continuous scale and, thus, reporting may be “off the scale” with specific conditions encountered in the space. This is not necessarily an error in EnergyPlus – rather a different approach that does not take the “limits” of the discrete scale values into account.

**1.14.2.2.27 Zone Thermal Comfort Fanger Model PMV []**

This field is the “predicted mean vote” (PMV) calculated using the Fanger thermal comfort model. Details on the equations used to calculate the Fanger PMV are shown in the EnergyPlus Engineering Reference. If the zone in question is currently being controlled using a thermostat object, then the value of the PMV is determined by using the air temperature and humidity that is calculated at the system time step; otherwise, if the zone is uncontrolled, the PMV is determined using the zone air temperature and humidity that is averaged over the zone time step.

**1.14.2.2.28 Zone Thermal Comfort Fanger Model PPD [%]**

This field is the “predicted percentage of dissatisfied” (PPD) calculated using the Fanger thermal comfort model. Details on the equations used to calculate the Fanger PPD are shown in the EnergyPlus Engineering Reference. If the zone in question is currently being controlled using a thermostat object, then the value of the PPD is determined by using the air temperature and humidity that is calculated at the system time step; otherwise, if the zone is uncontrolled, the PPD is determined using the zone air temperature and humidity that is averaged over the zone time step.

**1.14.2.2.29 Zone Thermal Comfort Clothing Surface Temperature [C]**

This output variable is the calculation of the clothing surface temperature using the Fanger thermal comfort model.

**1.14.2.2.30 Zone Thermal Comfort Pierce Model Effective Temperature PMV []**

This field is the “predicted mean vote” (PMV) calculated using the effective temperature and the Pierce two-node thermal comfort model.

**1.14.2.2.31 Zone Thermal Comfort Pierce Model Standard Effective Temperature PMV []**

This field is the “predicted mean vote” (PMV) calculated using the “standard” effective temperature and the Pierce two-node thermal comfort model.

**1.14.2.2.32 Zone Thermal Comfort Pierce Model Discomfort Index []**

This field is the “discomfort index” calculated using the the Pierce two-node thermal comfort model.

**1.14.2.2.33 Zone Thermal Comfort Pierce Model Thermal Sensation Index []**

This field is the “thermal sensation index” (PMV) calculated using the Pierce two-node thermal comfort model.

**1.14.2.2.34 Zone Thermal Comfort Pierce Model Standard Effective Temperature [C]**

This field is the “standard effective temperature” (SET) calculated using the Pierce two-node thermal comfort model. Note that if a user wishes to report the Pierce Model SET that it must be done using the Pierce two-node model and the user must select “Pierce” as one of the Thermal Comfort model types as shown above in the input syntax for the People statement.

**1.14.2.2.35 Zone Thermal Comfort KSU Model Thermal Sensation Vote []**

This field is the “thermal sensation vote” (TSV) calculated using the KSU two-node thermal comfort model.

**1.14.2.2.36 Zone Thermal Comfort ASHRAE 55 Adaptive Model 90% Acceptability Status []**

This field is to report whether the operative temperature falls into the 90% acceptability limits of the adaptive comfort in ASHRAE 55-2010. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable (when unoccupied or running average outdoor temp is outside the range of 10.0 to 33.5C).

**1.14.2.2.37 Zone Thermal Comfort ASHRAE 55 Adaptive Model 80% Acceptability Status []**

This field is to report whether the operative temperature falls into the 80% acceptability limits of the adaptive comfort in ASHRAE 55-2010. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable (when unoccupied or running average outdoor temp is outside the range of 10.0 to 33.5C).

**1.14.2.2.38 Zone Thermal Comfort ASHRAE 55 Adaptive Model Running Average Outdoor Air Temperature [C]**

This field reports the mean monthly outdoor air temperature, an input parameter for the ASHRAE-55 adaptive comfort model. This can be computed in two ways. If the .stat file is provided for the simulation, this field will reflect the monthly daily average temperature.

If the .epw file is used, the field reports the simple running average of the daily average outdoor dry-bulb temperatures of the previous 30 days.

**1.14.2.2.39 Zone Thermal Comfort ASHRAE 55 Adaptive Model Temperature [C]**

This field reports the ideal indoor operative temperature, or comfort temperature, as determined by the ASHRAE-55 adaptive comfort model. The 80% acceptability limits for indoor operative temperature are defined as no greater than 3.5 degrees C from the adaptive comfort temperature. The 90% acceptability limits are defined as no greater than 2.5 degrees C from the adaptive comfort temperature. A value of -1 means not applicable (when running average outdoor temp is outside the range of 10.0 to 33.5C).

**1.14.2.2.40 Zone Thermal Comfort CEN 15251 Adaptive Model Category I Status**

This field is to report whether the operative temperature falls into the Category I (90% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable (when unoccupied or running average outdoor temp is outside the range of 10.0 to 30.0C).

**1.14.2.2.41 Zone Thermal Comfort CEN 15251 Adaptive Model Category II Status**

This field is to report whether the operative temperature falls into the Category II (80% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable (when unoccupied or running average outdoor temp is outside the range of 10.0 to 30.0C).

**1.14.2.2.42 Zone Thermal Comfort CEN 15251 Adaptive Model Category III Status**

This field is to report whether the operative temperature falls into the Category III (65% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable (when unoccupied or running average outdoor temp is outside the range of 10.0 to 30.0C).

**1.14.2.2.43 Zone Thermal Comfort CEN 15251 Adaptive Model Running Average Outdoor Air Temperature**

This field reports the weighted average of the outdoor air temperature of the previous seven days, an input parameter for the CEN-15251 adaptive comfort model.

**1.14.2.2.44 Zone Thermal Comfort CEN 15251 Adaptive Model Temperature**

This field reports the ideal indoor operative temperature, or comfort temperature, as determined by the CEN-15251 adaptive comfort model. Category I, II, and III limits for indoor operative temperature are defined as no greater than 2, 3, and 4 degrees C from this value respectively. A value of -1 means not applicable (when running average outdoor temp is outside the range of 10.0 to 30.0C).

#### **1.14.2.2.45 Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect**

This field is the calculated Cooling Effect of the elevated air speed in degree celsius. It is the value that, when subtracted equally from both the average air temperature and the mean radiant temperature, yields the same SET under still air as in the first SET calculation under elevated air speed.

#### **1.14.2.2.46 Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect Adjusted PMV**

This field is the “predicted mean vote” (PMV) calculated using the Fanger PMV model, adjusted by the ASHRAE 55 Elevated Air Speed Cooling Effect. The Cooling Effect adjusted PMV for an environment with elevated average air speed is calculated using the adjusted average air temperature, the adjusted radiant temperature, and still air (0.1 m/s).

#### **1.14.2.2.47 Zone Thermal Comfort ASHRAE 55 Elevated Air Speed Cooling Effect Adjusted PPD**

This field is the “predicted percentage of dissatisfied” (PPD) calculated using the Fanger PMV-PPD model, adjusted by the ASHRAE 55 Elevated Air Speed Cooling Effect. The Cooling Effect adjusted PPD for an environment with elevated average air speed is calculated using the adjusted average air temperature, the adjusted radiant temperature, and still air (0.1 m/s).

#### **1.14.2.2.48 Zone Thermal Comfort ASHRAE 55 Ankle Draft PPD**

This field is the “predicted percentage of dissatisfied” (PPD) on draft at ankle level. It is used as the metric to evaluate the ankle draft risk as a function of PMV and air speed at the ankle level (0.1 m).

### **1.14.2.3 Outputs**

The following output variables are all based on whether the humidity ratio and the operative temperature is within the region shown in ASHRAE Standard 55-2004 in Figure 5.2.1.1. For these outputs the operative temperature is simplified to be the average of the air temperature and the mean radiant temperature. For summer, the 0.5 Clo level is used and, for winter, the 1.0 Clo level is used. The graphs below are based on the following tables which extend the ASHRAE values to zero humidity ratio.

Table 1.26: Winter Clothes (1.0 Clo)

Operative Temperature (C)	Humidity Ratio (kgWater/kgDryAir)
19.6	0.012
23.9	0.012
26.3	0.000
21.7	0.000

Table 1.27: Summer Clothes (0.5 Clo)

Operative Temperature (C)	Humidity Ratio (kgWater/kgDryAir)
23.6	0.012
26.8	0.012
28.3	0.000

Table 1.27: Summer Clothes (0.5 Clo)

Operative Temperature (C)	Humidity Ratio (kgWater/kgDryAir)
25.1	0.000

#### 1.14.2.3.1 Zone Thermal Comfort ASHRAE 55 Simple Model Summer Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

#### 1.14.2.3.2 Zone Thermal Comfort ASHRAE 55 Simple Model Winter Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

#### 1.14.2.3.3 Zone Thermal Comfort ASHRAE 55 Simple Model Summer or Winter Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

#### 1.14.2.3.4 Facility Thermal Comfort ASHRAE 55 Simple Model Summer Clothes Not Comfortable Time[hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

#### 1.14.2.3.5 Facility Thermal Comfort ASHRAE 55 Simple Model Winter Clothes Not Comfortable Time [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

#### 1.14.2.3.6 Facility Thermal Comfort ASHRAE 55 Simple Model Summer or Winter Clothes Not Comfortable Time [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

### 1.14.3 Simplified ASHRAE 55 Warnings

The simplified ASHRAE 55 calculations may be computed for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment. To enable this option set the “Enable ASHRAE 55 comfort warnings” field of the **People** object to Yes. These warnings will not be generated by default.

If you enable the warnings, the simplified ASHRAE 55 calculations are done for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment.

```
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF1
** ~~~ ** 553.0 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
** ~~~ ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\# = 725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF1
```

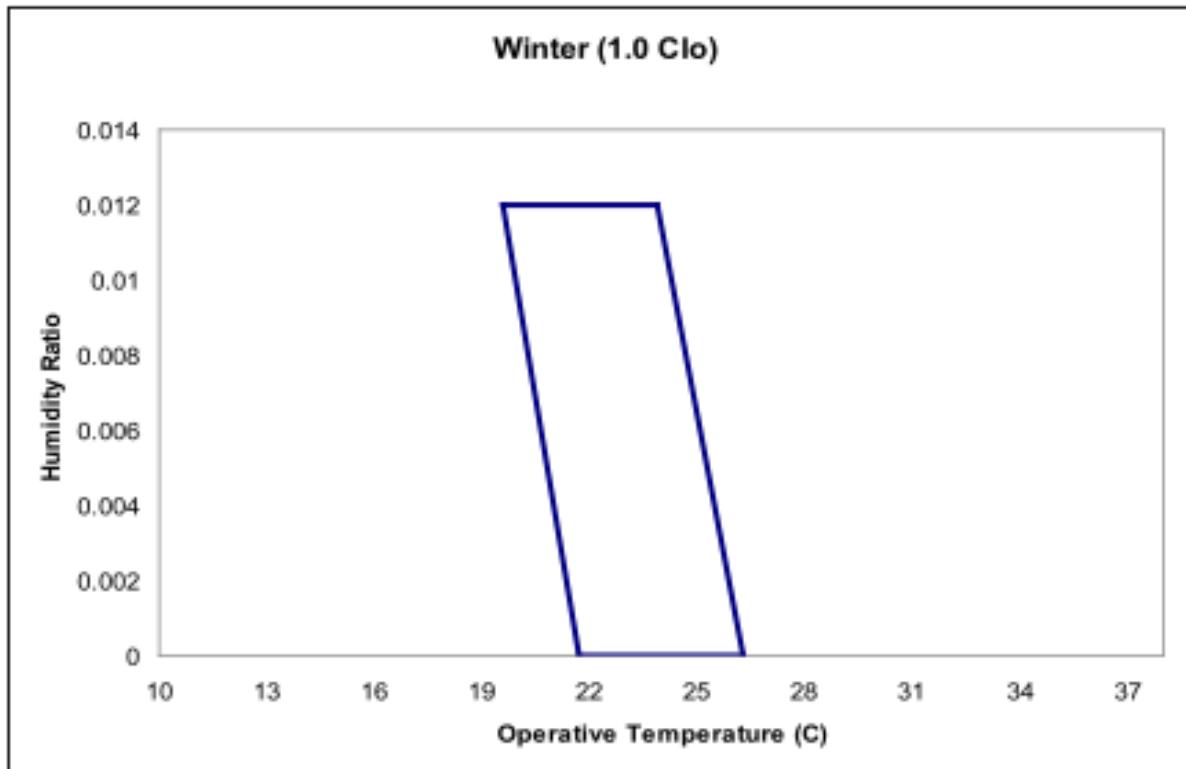

Figure 1.70: Winter Comfort Range

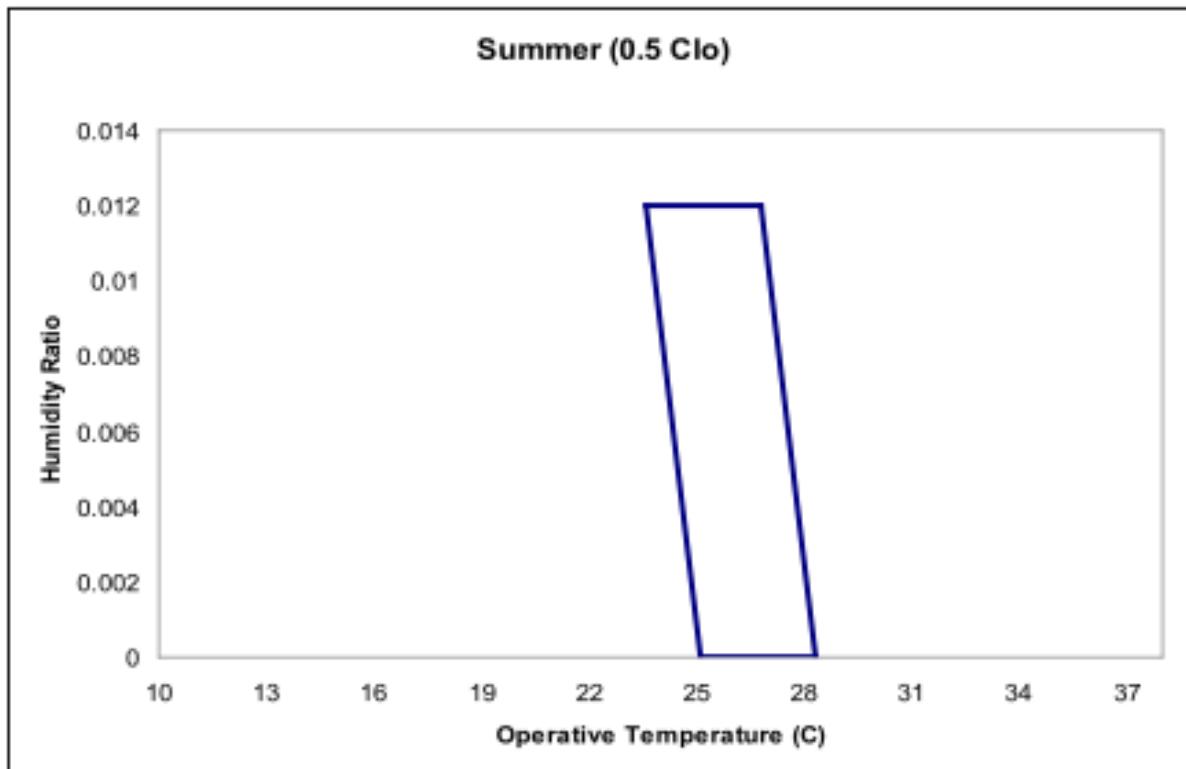

Figure 1.71: Summer Comfort Range

```
** ~~~ ** 827.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
** ~~~ ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\# = 725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF2
** ~~~ ** 593.5 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
** ~~~ ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\# = 725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF2
** ~~~ ** 875.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
** ~~~ ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\# = 725300
```

You may decide if you need to change parameters to reduce these “uncomfortable” hours. The individual output variables shown previously may help you get more details on when these are occurring.

Following are some suggestions that might be applicable:

- Eliminate occupancy when conditioning equipment is off.
- Note that the ASHRAE graph lower limit is (19.6C to 21.7C) – heating setpoints may need to be nearer 22.2C (72F) than 21.1C (70F).
- Unoccupied heating setpoint should be nearer 16.7C (62F) rather than 12.8C (55F) to reduce the start up recovery.
- Start the occupied setpoint schedule, fan availability schedule, cooling pump availability schedule, reheat coil availability, one hour before occupancy. Seasonal turn on and off of equipment may cause more warnings (but potentially more energy consumption).
- Unoccupied cooling setpoint should be nearer 29.4C (85F) rather than 40.0 (104F) to reduce the start up recovery.

## 1.14.4 ComfortViewFactorAngles

When requesting EnergyPlus to do a thermal comfort calculation, the program user has three options for defining how the mean radiant temperature will be calculated. The user may select “zoneaveraged” which results in a mean radiant temperature that is characteristic of an “average” location near the center of the zone. The user may also elect to place the person near a particular surface by selecting “surfaceweighted” in the **People** statement. This takes the average of the zone mean radiant temperature and the temperature of the surface that the person is near and uses this value as the mean radiant temperature when calculating thermal comfort.

The third option is for the user to more explicitly position the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The AngleFactorList input line is intended to give the user this opportunity.

### 1.14.4.1 Inputs

#### 1.14.4.1.1 Field: Name

This field is an unique user assigned name for the list of surfaces that can be seen radiantly by the person for whom thermal comfort is to be evaluated. Any reference to this list by a **People** statement will use this name.

#### 1.14.4.1.2 Field: Zone Name

Zone Name for this surface list. Each of the surfaces listed must be in this zone.

#### 1.14.4.1.3 Field: Surface <#> Name

This field is the name of a surface in the zone seen by the person.

#### 1.14.4.1.4 Field: Angle Factor <#>

This field is the fraction that this surface contributes to the total mean radiant temperature. This can be thought of as a weighting factor for this surface and the actual mean radiant temperature used in the thermal comfort model is simply the sum of all angle factors multiplied by the corresponding inside surface temperature. The sum of all angle factors within any angle factor list must equal unity, otherwise the program will not accept the input as valid.

Note that the Surface Name/Angle Factor pair is extensible to accommodate as many surfaces as required.

An example IDF with an electric low temperature radiant system is shown below.

```
ComfortViewFactorAngles,
South Zone Angle Factors, !- name of angle factor list
South Zone,           !- Zone Name
Zn001:Flr001,        !- Surface name 1
0.75,                !- Angle factor for surface 1
Zn001:Wall001,       !- Surface name 2
0.15,                !- Angle factor for surface 2
Zn001:Roof001,       !- Surface name 3
0.10;                !- Angle factor for surface 3
```

## 1.14.5 Lights

The Lights statement allows you to specify information about a zone's electric lighting system, including design power level and operation schedule, and how the heat from lights is distributed thermally.

A zone may have multiple Lights statements. For example, one statement may describe the general lighting in the zone and another the task lighting. Or you can use multiple Lights statements for a zone that has two or more general lighting systems that differ in design level, schedule, etc.

### 1.14.5.1 Inputs

#### 1.14.5.1.1 Field: Name

The name of the Lights object.

#### 1.14.5.1.2 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this Lights object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying lighting load at the same density in each zone or space. The names of the actual lights objects may be concatenated as <Space Name> <Lights Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

#### 1.14.5.1.3 Field: Schedule Name

The name of the schedule that modifies the lighting power design level (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The electrical input for lighting in a particular timestep is the product of the design level and the value of this schedule in that timestep. If the design level is the maximum lighting power input the schedule should contain values between 0.0 and 1.0.

#### 1.14.5.1.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal lighting level in the Zone. The key/choices are:

- LightingLevel

With this choice, the method used will be a straight insertion of the lighting level (Watts) for the Zone. (The Lighting Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

- Watts/Person

With this choice, the method used will be a factor of lighting level (watts) per person. (The Watts per person field should be filled).

#### **1.14.5.1.5 Field: Lighting Level**

This is typically the maximum electrical power input (in Watts) to lighting in a zone, including ballasts, if present. This value is multiplied by a schedule fraction (see previous field) to get the lighting power in a particular timestep. In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers.

#### **1.14.5.1.6 Field: Watts per Zone Floor Area**

This factor (watts/m<sup>2</sup>) is used, along with the Zone Floor Area to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/area”.

#### **1.14.5.1.7 Field: Watts per Person**

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/person”.

#### **1.14.5.1.8 Heat Gains from Lights:**

The electrical input to lighting ultimately appears as heat that contributes to zone loads or to return air heat gains. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Return Air Fraction, Fraction Radiant and Fraction Visible. A fourth, defined as the fraction of the heat from lights convected to the zone air, is calculated by the program as:

$$f_{convected} = 1.0 - (\text{Return Air Fraction} + \text{Fraction Radiant} + \text{Fraction Visible})$$

You will get an error message if Return Air Fraction + Fraction Radiant + Fraction Visible exceeds 1.0.

These fractions depend on the type of lamp and luminaire, whether the luminaire is vented to the return air, etc.

#### **1.14.5.1.9 Field: Return Air Fraction**

The fraction of the heat from lights that goes into the zone return air (i.e., into the zone outlet node). If the return air flow is zero or the zone has no return air system, the program will put this fraction into the zone air. Return Air Fraction should be non-zero only for luminaires that are return-air ducted (see Table 1.28 and Figure 51). (However, see the field “Return Air Fraction Is Calculated from Plenum Temperature,” below, for an approach to modeling the case where Return Air Fraction is caused by *conduction* between a luminaire that is in contact with a return-air plenum.)

#### 1.14.5.1.10 Field: Fraction Radiant

The fraction of heat from lights that goes into the zone as long-wave (thermal) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times thermal absorptance product of these surfaces.

#### 1.14.5.1.11 Field: Fraction Visible

The fraction of heat from lights that goes into the zone as visible (short-wave) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times solar absorptance product of these surfaces.

Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible are given in Table 1.28 for overhead fluorescent lighting for a variety of luminaire configurations. The data is based on ASHRAE 1282-RP “Lighting Heat Gain Distribution in Buildings” by Daniel E. Fisher and Chanvit Chantrasrisalai.

Table 1.28: Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible for overhead fluorescent lighting for different luminaire configurations.

Fixture No.	Luminaire Feature	Return Air Fraction	Fraction Radiant	Fraction Visible	fconvected
1	Recessed, Parabolic Louver, Non-Vented, T8	0.31	0.22	0.20	0.27
2	Recessed, Acrylic Lens, Non-Vented, T8	0.56	0.12	0.20	0.12
3	Recessed, Parabolic Louver, Vented, T8	0.28	0.19	0.20	0.33
4	Recessed, Acrylic Lens, Vented, T8	0.54	0.10	0.18	0.18
5	Recessed, Direct/Indirect, T8	0.34	0.17	0.16	0.33
6	Recessed, Volumetric, T5	0.54	0.13	0.20	0.13
7	Downlights, Compact Fluorescent, DTT	0.86	0.04	0.10	0.00
8	Downlights, Compact Fluorescent, TRT	0.78	0.09	0.13	0.00
9a	Downlights, Incandescent, A21	0.29	0.10	0.6	0.01
9b	Downlights, Incandescent, BR40	0.21	0.08	0.71	0.00
10	Surface Mounted, T5HO	0.00	0.27	0.23	0.50
11	Pendant, Direct/Indirect, T8	0.00	0.32	0.23	0.45

Table 1.28: Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible for overhead fluorescent lighting for different luminaire configurations.

Fixture No.	Luminaire Feature	Return Air Fraction	Fraction Radiant	Fraction Visible	$f_{\text{convected}}$
12	Pendant, Indirect, T5HO	0.00	0.32	0.25	0.43

5	Recessed, Direct/Indirect, T8 - Half Typical Supply Airflow Rate	0.04	0.13	0.16	0.67

#### 1.14.5.1.12 Field: Fraction Replaceable

This field defines the daylighting control for the LIGHTS object.

If **Daylighting:Controls** is specified for the space or zone, this field is used as an on/off flag for dimming controls. If set to 0.0, the lights are not dimmed by the daylighting controls. If set to 1.0, the lights are allowed to be dimmed by the applicable daylighting control. If daylighting controls are operating in the space or zone, all of the applicable Lights objects with a Fraction Replaceable greater than zero will be reduced by a multiplicative factor that accounts for how much the electric lighting is lowered due to daylighting (ref. [Daylighting Lighting Power Multiplier](#)).

#### 1.14.5.1.13 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Task Lights”, “Hall Lights”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and the LEED EAp2-4/5. Performance Rating Method Compliance table.

#### 1.14.5.1.14 Field: Return Air Fraction Calculated from Plenum Temperature

Accepts values Yes or No (the default). Yes is for advanced used only. In this case the program will calculate the return air fraction by assuming that it is due to conduction of some of the light heat into the zone’s return air plenum and that the amount of the conduction depends on the plenum air temperature. A Yes value should only be used for luminaires that are recessed and non-vented, as shown in Figure 1.72.

The value you enter for the Return Air Fraction field will be ignored and you can enter, for fluorescent lighting, Fraction Radiant = 0.37 and Fraction Visible = 0.18, as indicated in Table 1.28.

This feature requires that the coefficients described below be determined from measurements or detailed calculations since they are very sensitive to the luminaire type, lamp type, thermal resistance between fixture and plenum, etc.

If “Return Air Fraction Is Calculated from Plenum Temperature” = Yes, the return air fraction is calculated *each timestep* from the following empirical correlation:

$$(ReturnAirFraction)_{calculated} = C_1 - C_2 \times T_{plenum} \quad (1.24)$$

where  $T_{plenum}$  is the previous-time-step value of the return plenum air temperature (C), and  $C_1$  and  $C_2$  are the values of the coefficients entered in the next two fields.

To compensate for the change in the return air fraction relative to its input value, the program modifies Fraction Radiant and  $f_{convected}$  by a scale factor such that

$$(ReturnAirFraction)_{calculated} + (FractionRadiant)_{modified} + (f_{convected})_{modified} + (FractionVisible)_{input} = 1.0 \quad (1.25)$$

It is assumed that Fraction Visible is a constant equal to its input value.

#### 1.14.5.1.15 Field: Return Air Fraction Function of Plenum Temperature Coefficient 1

The coefficient  $C_1$  in the equation for  $(Return Air Fraction)_{calculated}$ .

#### 1.14.5.1.16 Field: Return Air Fraction Function of Plenum Temperature Coefficient 2

The coefficient  $C_2$  in the equation for  $(Return Air Fraction)_{calculated}$ . Its units are  $1^{\circ}\text{C}$ .

#### 1.14.5.1.17 Field: Return Air Heat Gain Node Name

Name of the return air node for this heat gain. If left blank, it defaults to the first return air node for the zone containing this Lights object. Leave blank when using a [ZoneList](#) name.

#### 1.14.5.1.18 Field:Exhaust Air Heat Gain Node Name

Name of the exhaust air node for this heat gain. If left blank, no heat gain from return air fraction will be added to the zone exhaust node. When the exhaust node name is entered, the return air heat gain will be shared by both return and exhaust nodes. The equipment can draw air from the exhaust node, but the inlet air properties are combined properties with mixing mass flow rates of both nodes and added lights heat gain.

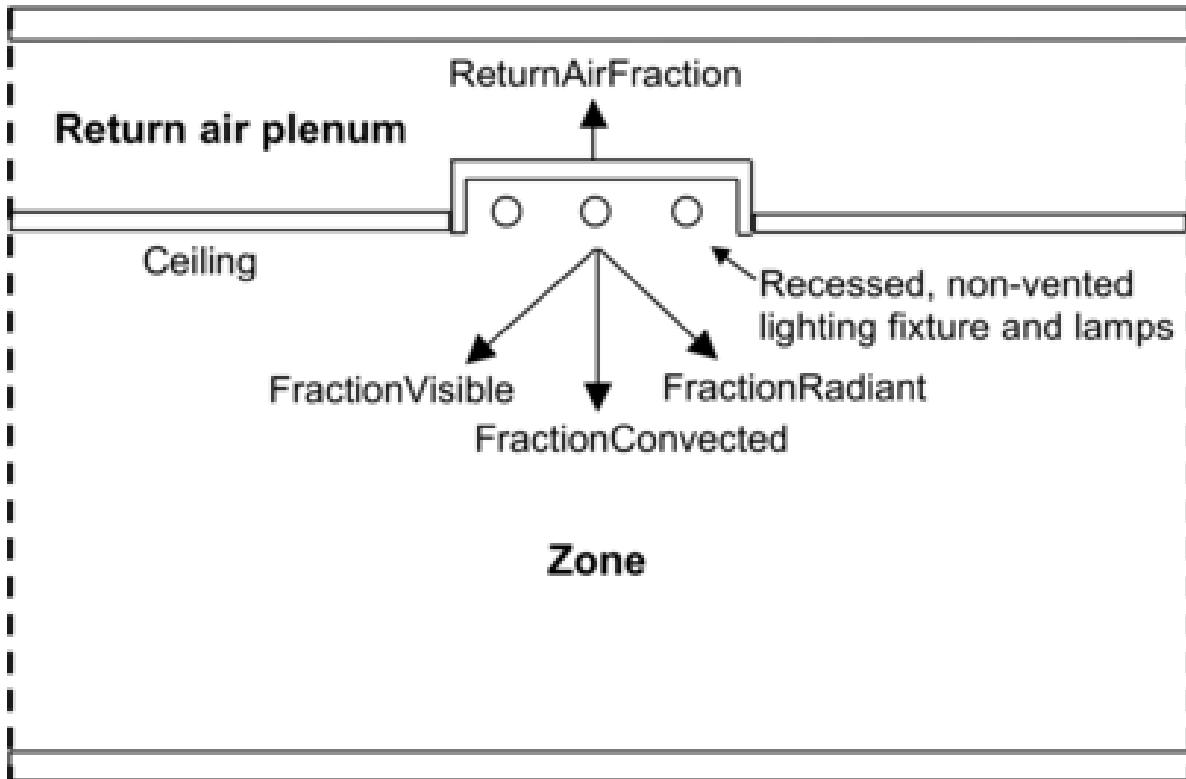

Figure 1.72: Vertical section through a zone and its return air plenum showing recessed lighting (not to scale). The heat from lights is divided into four fractions, three of which — ReturnAirFraction, FractionRadiant and FractionConvected — depend on plenum air temperature.

- Zone,Average,Zone Lights Total Heating Rate [W]
- Zone,Sum,Zone Lights Electricity Energy [J]

#### **1.14.5.2.1 Lights Radiant Heating Rate [W]**

#### **1.14.5.2.2 Lights Radiant Heating Energy [J]**

The amount of heat gain from lights that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times long-wave absorptance weighting scheme.

#### **1.14.5.2.3 Lights Visible Radiation Heating Rate [W]**

#### **1.14.5.2.4 Lights Visible Radiation Heating Energy [J]**

The amount of heat gain from lights that is in the form of visible (short-wave) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times short-wave absorptance weighting scheme.

#### **1.14.5.2.5 Lights Convective Heating Rate [W]**

#### **1.14.5.2.6 Lights Convective Heating Energy [J]**

The amount of heat gain from lights that is convected to the zone air.

#### **1.14.5.2.7 Lights Return Air Heating Rate [W]**

#### 1.14.5.2.8 Lights Return Air Heating Energy [J]

The amount of heat gain from lights that goes into the zone's return air (and, therefore, does not directly contribute to the zone load). If the zone has no return air system or the zone's air system is off, this heat will be added to the zone air.

#### 1.14.5.2.9 Lights Total Heating Rate [W]

#### 1.14.5.2.10 Lights Total Heating Energy [J]

The total heat gain from lights. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

#### 1.14.5.2.11 Lights Electricity Rate [W]

The electric power input for the lights.

#### 1.14.5.2.12 Lights Electricity Energy [J]

The lighting electrical consumption including ballasts, if present. This will have the same value as Lights Total Heating Energy (above). The energy amount is also included in the following Electricity meters:

```
Electricity:Facility
Electricity:Building
Electricity:Zone:<Zone Name>
Electricity:SpaceType:<Space Type Name>
InteriorLights:Electricity
InteriorLights:Electricity:Zone:<Zone Name>
InteriorLights:Electricity:SpaceType:<Space Type Name>
<End-Use Subcategory>:InteriorLights:Electricity
<End-Use Subcategory>:InteriorLights:Electricity:Zone:<Zone Name>
<End-Use Subcategory>:InteriorLights:Electricity:SpaceType:<Space Type Name>
```

---

#### 1.14.5.2.13 Space or Zone Lights Radiant Heating Rate [W]

#### 1.14.5.2.14 Space or Zone Lights Radiant Heating Energy [J]

The amount of heat gain from all lights in the space or zone that is in the form of long-wave (thermal) radiation entering the space or zone. This heat is absorbed by the inside surfaces of the space or zone according to an area times long-wave absorptance weighting scheme.

#### 1.14.5.2.15 Space or Zone Lights Visible Radiation Heating Rate [W]

#### 1.14.5.2.16 Space or Zone Lights Visible Radiation Heating Energy [J]

The amount of heat gain from all lights in the space or zone that is in the form of visible (short-wave) radiation entering the space or zone. This heat is absorbed by the inside surfaces of the space or zone according to an area times short-wave absorptance weighting scheme.

#### 1.14.5.2.17 Space or Zone Lights Convective Heating Rate [W]

#### 1.14.5.2.18 Space or Zone Lights Convective Heating Energy [J]

The amount of heat gain from all lights in the space or zone that is convected to the space or zone air.

#### 1.14.5.2.19 Space or Zone Lights Return Air Heating Rate [W]

**1.14.5.2.20 Space or Zone Lights Return Air Heating Energy [J]**

The amount of heat gain from all lights in the space or zone that goes into the space or zone's return air (and, therefore, does not directly contribute to the space or zone load). If the space or zone has no return air system or the space or zone's air system is off, this heat will be added to the space or zone air.

**1.14.5.2.21 Space or Zone Lights Total Heating Rate [W]****1.14.5.2.22 Space or Zone Lights Total Heating Energy [J]**

The total heat gain from all lights in the space or zone. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

**1.14.5.2.23 Space or Zone Lights Electricity Rate [W]****1.14.5.2.24 Space or Zone Lights Electricity Energy [J]**

The electric power input for all lights in the space or zone. This will have the same value as Zone Lights Total Heating Rate or Energy (above).

## 1.14.6 ElectricEquipment

The object models equipment in the zone which consumes electricity, such as computers, televisions, and cooking equipment, also known as "plug loads." All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below.

### 1.14.6.1 Inputs

**1.14.6.1.1 Field: Name**

The name of the ElectricEquipment object.

**1.14.6.1.2 Field: Zone or ZoneList or Space or SpaceList Name**

This field applies this ElectricEquipment object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying equipment load at the same density in each zone or space. The names of the actual electric equipment objects may be concatenated as <Space Name> <ElectricEquipment Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

**1.14.6.1.3 Field: Schedule Name**

This field is the name of the schedule that modifies the design level parameter for electric equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual electrical input for equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

**1.14.6.1.4 Field: Design Level Calculation Method**

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal electric equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the electric equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

- Watts/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Watts per Person field should be filled).

#### **1.14.6.1.5 Field: Design Level**

This field (in Watts) is typically used to represent the maximum electrical input to equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the electric equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### **1.14.6.1.6 Field: Watts per Zone Floor Area**

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Area”.

#### **1.14.6.1.7 Field: Watts per Person**

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Person”.

#### **1.14.6.1.8 Heat Gains from Electric Equipment:**

The electrical input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{FractionLatent} + \text{FractionRadiant} + \text{FractionLost}) \quad (1.26)$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### **1.14.6.1.9 Field: Fraction Latent**

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of latent energy produced by the electric equipment. This energy affects the moisture balance within the zone.

#### **1.14.6.1.10 Field: Fraction Radiant**

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of long wavelength radiation gain from electric equipment in a zone.

### 1.14.6.1.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of “lost” heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of heat which is “lost” and does not impact the zone energy balances. This might correspond to electrical energy converted to mechanical work or heat that is vented to the atmosphere.

### 1.14.6.1.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Computers”, “Copy Machines”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and the LEED Summary table EAp2-4/5. Performance Rating Method Compliance.

An IDF example:

```
ElectricEquipment,
DORM ROOMS AND COMMON AREAS ElecEq 1, !- Name
DORM ROOMS AND COMMON AREAS, !- Zone Name
Residence Equipment, !- SCHEDULE Name
EquipmentLevel, !- Design Level calculation method
9210.921, !- Design Level {W}

, !- Watts per Zone Floor Area {W/m2}
96, !- Watts per Person {W/person}
0, !- Fraction Latent
0.3, !- Fraction Radian
0; !- Fraction Lost
```

## 1.14.7 GasEquipment

The object models equipment in the zone which consumes natural gas, such as cooking equipment or a gas fireplace. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below.

### 1.14.7.1 Inputs

#### 1.14.7.1.1 Field: Name

The name of the GasEquipment object.

#### **1.14.7.1.2 Field: Zone or ZoneList or Space or SpaceList Name**

This field applies this GasEquipment object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying equipment load at the same density in each zone or space. The names of the actual gas equipment objects may be concatenated as <Space Name> <GasEquipment Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

#### **1.14.7.1.3 Field: Schedule Name**

This field is the name of the schedule that modifies the design level parameter for gas equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for gas equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### **1.14.7.1.4 Field: Design Level Calculation Method**

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal gas equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the gas equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### **1.14.7.1.5 Field: Design Level**

This field (in Watts) is typically used to represent the maximum energy input to gas equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the gas equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### **1.14.7.1.6 Field: Power per Zone Floor Area**

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Area**” or “**Power/Area**”.

#### **1.14.7.1.7 Field: Power per Person**

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Person**” or “**Power/Person**”.

#### 1.14.7.1.8 Heat Gains from Gas Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from gas equipment convected to the zone air, is calculated by the program as:

$$f_{convected} = 1.0 - (\text{FractionLatent} + \text{FractionRadiant} + \text{FractionLost}) \quad (1.27)$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.14.7.1.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of latent energy produced by the gas equipment. This energy affects the moisture balance within the zone.

#### 1.14.7.1.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of long wavelength radiation gain from gas equipment in a zone.

#### 1.14.7.1.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of “lost” heat being given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of heat which is “lost” and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.14.7.1.12 Field: Carbon Dioxide Generation Rate

This numeric input field specifies carbon dioxide generation rate with units of m<sup>3</sup>/s-W. The default value of 0.0 assumes the equipment is fully vented to outdoors. In the absence of better information, the user might consider using a value of 3.45E-8 m<sup>3</sup>/s-W which assumes the equipment is not vented to outdoors. This value is converted from natural gas CO<sub>2</sub> emission rate at 11.7 lbs CO<sub>2</sub> per therm. The CO<sub>2</sub> emission rate is provided by U.S. Energy Information Administration, “Frequently Asked Questions - Environment, Questions About Environmental Emissions”, [http://tonto.eia.doe.gov/ask/environment\\_faqs.asp#CO2\\_quantity](http://tonto.eia.doe.gov/ask/environment_faqs.asp#CO2_quantity), January 2010. The maximum value for this input field is 3.45E-7 m<sup>3</sup>/s-W.

#### 1.14.7.1.13 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Cooking”, “Clothes Drying”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and the LEED Summary table EAp2-4/5 Performance Rating Method Compliance.

An IDF example:

```

                                !- Schedule Name
                                !- Design Level Calculation Method
                                !- Design Level {W}
                                !- Power per Zone Floor Area {W/m2}
                                !- Power per Person {W/Person}
                                !- Fraction Latent
                                !- Fraction Radiant
                                !- Fraction Lost

```

## 1.14.8 HotWaterEquipment

The object models hot water equipment in the zone which consumes district heating, such as cooking equipment or process loads. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below. This object consumes district heating energy directly and does not cause a load on a hot water plant loop or water heater. For domestic hot water uses, such as sinks and showers, see [WaterUse:Equipment](#).

### 1.14.8.1 Inputs

#### 1.14.8.1.1 Field: Name

The name of the HotWaterEquipment object.

#### 1.14.8.1.2 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this HotWaterEquipment object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying equipment load at the same density in each zone or space. The names of the actual hot water equipment objects may be concatenated as <Space Name> <HotWaterEquipment Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

#### 1.14.8.1.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for hot water equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for hot water equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.14.8.1.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal hot water equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the hot water equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### **1.14.8.1.5 Field: Design Level**

This field (in Watts) is typically used to represent the maximum energy input to hot water equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the hot water equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### **1.14.8.1.6 Field: Power per Zone Floor Area**

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Area**” or “**Power/Area**”.

#### **1.14.8.1.7 Field: Power per Person**

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Person**” or “**Power/Person**”.

#### **1.14.8.1.8 Heat Gains from Hot Water Equipment:**

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from hot water equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{FractionLatent} + \text{FractionRadiant} + \text{FractionLost}) \quad (1.28)$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### **1.14.8.1.9 Field: Fraction Latent**

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of latent energy produced by the hot water equipment. This energy affects the moisture balance within the zone.

#### 1.14.8.1.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of long wavelength radiation gain from hot water equipment in a zone.

#### 1.14.8.1.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of “lost” heat being given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of heat which is “lost” and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.14.8.1.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Cooking”, “Clothes Drying”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) obejct). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and the LEED Summary table EAp2-4/5 Performance Rating Method Compliance.

IDF Examples:

```
HotWaterEquipment,
  SPACE2-1 HWEq 1,      !- Name
  SPACE2-1,              !- Zone or ZoneList or Space or SpaceList Name
  EQUIP-1,               !- SCHEDULE Name

  0.0000000E+00,             !- Fraction Latent
  0.3000000,                  !- Fraction Radiant
  0.0000000E+00;             !- Fraction Lost
```

### 1.14.9 SteamEquipment

The object models steam equipment in the zone which consumes district heating, such as cooking equipment or process loads. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below. This object consumes district heating energy directly and does not cause a load on a steam plant loop.

### 1.14.9.1 Inputs

#### 1.14.9.1.1 Field: Name

The name of the SteamEquipment object.

#### 1.14.9.1.2 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this SteamEquipment object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying equipment load at the same density in each zone or space. The names of the actual steam equipment objects may be concatenated as <Space Name> <SteamEquipment Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

#### 1.14.9.1.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for steam equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for steam equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.14.9.1.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal steam equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the steam equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### 1.14.9.1.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to steam equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the steam equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.14.9.1.6 Field: Power per Zone Floor Area

This factor ( $\text{watts}/\text{m}^2$ ) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Area**” or “**Power/Area**”.

#### 1.14.9.1.7 Field: Power per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “**Watts/Person**” or “**Power/Person**”.

#### 1.14.9.1.8 Heat Gains from Steam Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from steam equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{FractionLatent} + \text{FractionRadiant} + \text{FractionLost}) \quad (1.29)$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.14.9.1.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of latent energy produced by the steam equipment. This energy affects the moisture balance within the zone.

#### 1.14.9.1.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of long wavelength radiation gain from steam equipment in a zone.

#### 1.14.9.1.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of “lost” heat being given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of heat which is “lost” and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.14.9.1.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Cooking”, “Clothes Drying”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and the LEED Summary table EAp2-4/5 Performance Rating Method Compliance.

IDF Examples:

```

## 1.14.10 OtherEquipment

Other Equipment object is provided as an additional source for heat gains or losses directly to the zone with a fuel type that is configurable. If a fuel type is specified, the energy is attributed to the appropriate end use. Otherwise, a loss can be entered by putting a negative value into the Design Level field and this object will not have an end-use component – gains or losses do not show up in the bottom energy lines (except as influencing overall zone gains or losses).

### 1.14.10.1 Inputs

#### 1.14.10.1.1 Field: Name

The name of the OtherEquipment object.

#### 1.14.10.1.2 Field: Fuel Type

This field designates the appropriate meter for the equipment. Valid fuel types are: None, Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, Steam, **DistrictHeating**, **DistrictCooling**, OtherFuel1 and OtherFuel2. The fuel type triggers the application of consumption amounts to the appropriate energy meters. If the None fuel type is selected (the default if left blank), no end uses will be associated with the object, only the zone gains.

#### 1.14.10.1.3 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this OtherEquipment object to one or more thermal zones or spaces in the building. The Zone, Zonelist or SpaceList options can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method to place a varying equipment load at the same density in each zone or space. The names of the actual other equipment objects may be concatenated as <Space Name> <OtherEquipment Object Name>. See **Specifying Applicable Zone(s) or Space(s)** for more details.

#### 1.14.10.1.4 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for other equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for other equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.14.10.1.5 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal other equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the other equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### **1.14.10.1.6 Field: Design Level**

This field (in Watts) is typically used to represent the maximum energy input to other equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the other equipment design level could be a “diversity factor” applied to a schedule of real numbers. This value can be negative to denote a loss if the None fuel type is selected, otherwise this must be positive. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### **1.14.10.1.7 Field: Power per Zone Floor Area**

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. This value can be negative to denote a loss if the None fuel type is selected, otherwise this must be positive. The choice from the method field should be “**Watts/Area**” or “**Power/Area**”.

#### **1.14.10.1.8 Field: Power per Person**

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. This value can be negative to denote a loss if the None fuel type is selected, otherwise this must be positive. The choice from the method field should be “**Watts/Person**” or “**Power/Person**”.

#### **1.14.10.1.9 Heat Gains/Losses from Other Equipment:**

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from other equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{FractionLatent} + \text{FractionRadiant} + \text{FractionLost}) \quad (1.30)$$

You will get an error message if FractionLatent + FractionRadiant + FractionLost exceeds 1.0.

#### **1.14.10.1.10 Field: Fraction Latent**

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of latent energy produced by the other equipment. This energy affects the moisture balance within the zone.

#### **1.14.10.1.11 Field: Fraction Radiant**

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of long wavelength radiation gain from other equipment in a zone.

#### 1.14.10.1.12 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of “lost” heat being given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of heat which is “lost” and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.14.10.1.13 Field: Carbon Dioxide Generation Rate

This numeric input field specifies carbon dioxide generation rate with units of m<sup>3</sup>/s-W. The default value of 0.0 assumes the equipment is fully vented to outdoors. The maximum value for this input field is 3.45E-7 m<sup>3</sup>/s-W.

#### 1.14.10.1.14 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Cooking”, “Clothes Drying”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table EAp2-4/5 Performance Rating Method Compliance.

#### 1.14.11.0.21 <Type> Equipment Radiant Heating Rate [W]

#### 1.14.11.0.22 <Type> Equipment Radiant Heating Energy [J]

#### 1.14.11.0.23 Space or Zone <Type> Equipment Radiant Heating Rate [W]

**1.14.11.0.24 Space or Zone <Type> Equipment Radiant Heating Energy [J]**

The amount of heat gain from equipment that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the space or zone according to an area times long-wave absorptance weighting scheme.

**1.14.11.0.25 <Type> Equipment Convective Heating Rate [W]****1.14.11.0.26 <Type> Equipment Convective Heating Energy [J]****1.14.11.0.27 Space or Zone <Type> Equipment Convective Heating Rate [W]****1.14.11.0.28 Space or Zone <Type> Equipment Convective Heating Energy [J]**

The amount of heat gain from equipment that is convected to the space or zone air.

**1.14.11.0.29 <Type> Latent Gain Rate [W]****1.14.11.0.30 <Type> Equipment Latent Gain Energy [J]****1.14.11.0.31 Space or Zone <Type> Latent Gain Rate [W]****1.14.11.0.32 Space or Zone <Type> Equipment Latent Gain Energy [J]**

The amount of heat gain from equipment that goes added to the space or zone air as a latent (moisture) gain.

**1.14.11.0.33 <Type> Lost Heat Rate [W]****1.14.11.0.34 <Type> Equipment Lost Heat Energy [J]****1.14.11.0.35 Space or Zone <Type> Lost Heat Rate [W]****1.14.11.0.36 Space or Zone <Type> Equipment Lost Heat Energy [J]**

The amount of energy input to the equipment that is removed (exhausted) and does not add any heat gain to the space or zone.

**1.14.11.0.37 <Type> Equipment Total Heating Rate [W]****1.14.11.0.38 <Type> Equipment Total Heating Energy [J]****1.14.11.0.39 Space or Zone <Type> Equipment Total Heating Rate [W]****1.14.11.0.40 Space or Zone <Type> Equipment Total Heating Energy [J]**

The total heat gain from equipment. It is the sum of the following components: Total Heat Gain = Radiant Heat Gain + Convective Heat Gain + Latent Heat Gain. It is also equal to the power input to the equipment minus any Lost Heat.

### 1.14.12 ElectricEquipment:ITE:AirCooled

This object describes air-cooled electric information technology equipment (ITE) which has variable power consumption as a function of loading and temperature.

#### 1.14.12.1 Inputs

##### 1.14.12.1.1 Field: Name

The name of this object.

##### 1.14.12.1.2 Field: Zone or Space Name

This field applies this ElectricEquipment:ITE:AirCooled object to a thermal zones or space in the building. If a Zone Name is specified and the zone contains more than one Space, the names of the actual IT equipment objects will be concatenated as <Space Name> <ITEquipment Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

##### 1.14.12.1.3 Field: Air Flow Calculation Method

This field specifies the method used to calculate the IT inlet temperature and zone return air temperature.

If **FlowFromSystem** is chosen, the zone is assumed to be well-mixed.

If **FlowControlWithApproachTemperatures** is chosen, Supply and Return approach temperature should be defined to indicate the temperature difference due to the air distribution. The inputs of *Air Inlet Connection Type*, *Design Recirculation Fraction* and *Recirculation Function of Loading and Supply Temperature Curve Name* are ignored. For multiple ITE objects defined for one zone, the same calculation method should apply. The **FlowControlWithApproachTemperatures** only applies to ITE zones with single duct VAV terminal unit. Other return air heat gains from window or lights are not allowed when **FlowControlWithApproachTemperatures** is chosen.

The default method is FlowFromSystem.

##### 1.14.12.1.4 Field: Design Power Input Calculation Method

This field is a key/choice field that tells which of the next two fields are filled and is descriptive of the method for calculating the nominal electric power input to the ITE. The key/choices are:

Watts/Unit

With this choice, the design power input will be the product of Design Level per Unit and Number of Units. (Both of these fields should be filled.) This is the default.

Watts/Area

With this choice, the design power input will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

##### 1.14.12.1.5 Field: Watts per Unit

This field (in Watts) is typically used to represent the design electrical power input to the ITE when fully loaded and the entering air temperatures is at the specified design value. This field is used if the choice from the method field is “EquipmentLevel”.

##### 1.14.12.1.6 Field: Number of Units

This field is multiplied times the Design Level per Unit to determine the design electrical power input to this ITE object when fully loaded and the entering air temperature is at the specified design value. This field is used if the choice from the method field is “EquipmentLevel”. The default is 1.

#### 1.14.12.1.7 Field: Watts per Zone Floor Area

This factor (Watts/m<sup>2</sup>) is used, along with the Zone Area to determine the design electrical power input as described in the Design Level field above. This field is used if the choice from the method field is “Watts/Area”.

#### 1.14.12.1.8 Field: Design Power Input Schedule Name

This field is the name of the operating schedule that modifies the design level power input for this equipment. This schedule specifies the fraction (typically 0.0 to 1.0) of this equipment which is available (powered up), regardless of CPU utilization. If this field is blank, the schedule is assumed to always be 1.0.

#### 1.14.12.1.9 Field: CPU Loading Schedule Name

This field is the name of the schedule that specifies the CPU loading for this equipment as a fraction from 0.0 (idle) to 1.0 (full load). If this field is blank, the schedule is assumed to always be 1.0.

#### 1.14.12.1.10 Field: CPU Power Input Function of Loading and Air Temperature Curve Name

The name of a two-variable curve or table lookup object which modifies the CPU power input as a function of CPU loading (x) and air inlet node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

#### 1.14.12.1.11 Field: Design Fan Power Input Fraction

This field is a decimal number between 0.0 and 1.0 and is used to specify the fraction of the total power input at design conditions which is for the cooling fan(s). If fan power data is not available, set this fraction to 0.0. The default is 0.0.

#### 1.14.12.1.12 Field: Design Fan Air Flow Rate per Power Input

Specifies the cooling fan air flow rate in m<sup>3</sup>/s per Watt of total electric power input at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

This is normalized by power input to allow the design power input to be changed without needing to change this value.

#### 1.14.12.1.13 Field: Air Flow Function of Loading and Air Temperature Curve Name

The name of a two-variable curve or table lookup object which modifies the cooling air flow rate as a function of CPU loading (x) and air inlet node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

#### 1.14.12.1.14 Field: Fan Power Input Function of Flow Curve Name

The name of a single-variable curve or table lookup object which modifies the fan power input as a function of airflow fraction (x). This curve (table) should equal 1.0 at the design air flow rate (flow fraction = 1.0).

#### 1.14.12.1.15 Field: Design Entering Air Temperature

Specifies the entering air temperature in deg. C at design conditions. The default is 15C.

#### **1.14.12.1.16 Field: Environmental Class**

Specifies the allowable operating conditions for the air inlet conditions. The available inputs are A1, A2, A3, A4, B, C, or None. This is used to report the “ITE Air Inlet Operating Range Exceeded Time” If None is specified (the default), then no reporting of time outside allowable conditions will be done.

#### **1.14.12.1.17 Field: Air Inlet Connection Type**

Specifies the type of connection between the zone and the ITE air inlet node. The choices are:

AdjustedSupply = This option is used to apply a recirculation adjustment to the ITE inlet conditions. If this option is specified, then the Supply Air Node Name is required and the air inlet temperature to the ITE will be the current supply air node temperature adjusted by the current recirculation fraction. All heat output is added to the zone air heat balance as a convective gain. AdjustedSupply is the default.

ZoneAirNode = This option is used if there is no containment and the ITE air inlet node is at the average zone condition. All heat output is added to the zone air heat balance as a convective gain.

RoomAirModel = This option connects the ITE air inlet and outlet nodes to a room air model (Ref. [RoomAirModelType](#) and [RoomAir:Node](#)). Currently in EnergyPlus, this option has not been fully implemented. If the user chooses this option, the program will issue a warning message and this field will be adjusted to ZoneAirNode.

This field is only used when Air Flow Calculation Method is **FlowFromSystem**.

#### **1.14.12.1.18 Field: Air Inlet Room Air Model Node Name**

Specifies the name of a room air model node (ref. [RoomAir:Node](#)) which is the air inlet to this equipment. This field is required if the Air Node Connection Type = RoomAirModel.

#### **1.14.12.1.19 Field: Air Outlet Room Air Model Node Name**

Specifies the node name of a room air model node (ref. [RoomAir:Node](#)) which is the air outlet from this equipment. This field is required if the Air Node Connection Type = RoomAirModel.

#### **1.14.12.1.20 Field: Supply Air Node Name**

Specifies the node name of the supply air inlet node service this ITE. If the Air Node Connection Type = AdjustedSupply ,then this field is required, and the conditions at this node will be used to determine the ITE air inlet conditions. This field is also required if reporting of the Supply Heat Index is desired. Also required if Calculation Method = **FlowControlWithApproachTemperatures**.

#### **1.14.12.1.21 Field: Design Recirculation Fraction**

Specifies the recirculation fraction for this equipment at design conditions. This field is used only if the Air Node Connection Type = AdjustedSupply. The recirculation fraction is defined as the ratio of recirculated air flow to total air flow entering the ITE. Recirculation is dependent upon many factors including rack and containment configuration. The default is 0.0 (no recirculation). This field is only used when Air Flow Calculation Method = **FlowFromSystem**.

#### **1.14.12.1.22 Field: Recirculation Function of Loading and Supply Temperature Curve Name**

The name of a two-variable curve or table lookup object which modifies the Design Recirculation Fraction as a function of CPU loading (x) and supply air node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature). This field is used only if the Air Node Connection Type = AdjustedSupply. If this curve is left blank, then the curve is assumed to always equal 1.0. This field is only used when Air Flow Calculation Method = **FlowFromSystem**.

#### **1.14.12.1.23 Field: Design Electric Power Supply Efficiency**

This field is a decimal number used to specify the efficiency of the power supply system serving this ITE. The default is 1.0.

#### **1.14.12.1.24 Field: Electric Power Supply Efficiency Function of Part Load Ratio Curve Name**

The name of a single-variable curve or table lookup object which modifies the electric power supply efficiency as a function of part load ratio (x). This curve (table) should equal 1.0 at the design power consumption (part load ratio = 1.0). If this curve is left blank, then the curve is assumed to always equal 1.0.

#### **1.14.12.1.25 Field: Fraction of Electric Power Supply Losses to Zone**

This field is a decimal number between 0.0 and 1.0 and is used to specify the fraction of the electric power supply losses which are a heat gain to the zone containing the ITE. If this value is less than 1.0, the remainder of the losses are assumed to be lost to the outdoors. The default is 1.0.

#### **1.14.12.1.26 Field: CPU End-Use Subcategory**

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the CPU power consumption. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) object). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table EAp2-4/5 Performance Rating Method Compliance. The default is ITE-CPU.

#### **1.14.12.1.27 Field: Fan End-Use Subcategory**

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the fan power consumption. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) object). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table EAp2-4/5 Performance Rating Method Compliance. The default is ITE-Fans

#### **1.14.12.1.28 Field: Electric Power Supply End-Use Subcategory**

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the electric power supply power consumption. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) object). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table EAp2-4/5 Performance Rating Method Compliance. The default is ITE-UPS

#### **1.14.12.1.29 Field: Supply Temperature Difference**

The difference of the IT inlet temperature from the AHU supply air temperature ( $\delta T_{supply} = T_{in} - T_{supply}$ ). Either Supply Temperature Difference or Supply Temperature Difference Schedule is required if Air Flow Calculation Method is set to **FlowControlWithApproachTemperatures**. This field is ignored when Air Flow Calculation Method is **FlowFromSystem**.

#### **1.14.12.1.30 Field: Supply Temperature Difference Schedule**

The difference schedule of the IT inlet temperature from the AHU supply air temperature ( $\delta T_{supply} = T_{in} - T_{supply}$ ). Either Supply Temperature Difference or Supply Temperature Difference Schedule is required if Air Flow Calculation Method is set to **FlowControlWithApproachTemperatures**. This field is ignored when Air Flow Calculation Method is **FlowFromSystem**.

### 1.14.12.1.31 Field: Return Temperature Difference

The difference of the actual AHU return air temperature to the IT equipment outlet temperature ( $\delta T_{return} = T_{return} - T_{out}$ ). Either Return Temperature Difference or Return Temperature Difference Schedule is required if Air Flow Calculation Method is set to **FlowControlWithApproachTemperatures**. This field is ignored when Air Flow Calculation Method is **FlowFromSystem**.

### 1.14.12.1.32 Field: Return Temperature Difference Schedule

The difference schedule of the actual AHU return air temperature to the IT equipment outlet temperature ( $\delta T_{return} = T_{return} - T_{out}$ ). Either Return Temperature Difference or Return Temperature Difference Schedule is required if Air Flow Calculation Method is set to **FlowControlWithApproachTemperatures**. This field is ignored when Air Flow Calculation Method is **FlowFromSystem**.

#### 1.14.12.1.33 Space or Zone ITE CPU Electricity Rate [W]

#### 1.14.12.1.34 ITE CPU Electricity Rate [J]

#### 1.14.12.1.35 Space or Zone ITE CPU Electricity Energy [J]

#### 1.14.12.1.36 ITE CPU Electricity Energy [J]

The electric power (or energy) input to the ITE equipment CPU (total power input less cooling fan power). The ITE CPU Electricity Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. [Output:Meter](#) object).

#### 1.14.12.1.37 Space or Zone ITE CPU Electricity Rate at Design Inlet Conditions [W]

#### 1.14.12.1.38 ITE CPU Electricity Rate at Design Inlet Conditions [W]

#### 1.14.12.1.39 Space or Zone ITE CPU Electricity Energy at Design Inlet Conditions [J]

#### 1.14.12.1.40 ITE CPU Electricity Energy at Design Inlet Conditions [J]

The electric power (or energy) input to the ITE equipment CPU (total power input less cooling fan power) if the air inlet temperature were held at the design condition. May be used to calculate “IT efficiency”, the ratio of (IT energy consumed in the facility) / (IT energy that would have been consumed in the facility if the ITE were held at the reference temperature).

#### 1.14.12.1.41 Space or Zone ITE Fan Electricity Rate [W]

#### 1.14.12.1.42 ITE Fan Electricity Rate [W]

#### 1.14.12.1.43 Space or Zone ITE Fan Electricity Energy [J]

#### 1.14.12.1.44 ITE Fan Electricity Energy [J]

The electric power (or energy) input to the ITE cooling fan. The ITE Fan Electricity Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. [Output:Meter](#) object).

#### 1.14.12.1.45 Space or Zone ITE Fan Electricity Rate at Design Inlet Conditions [W]

#### 1.14.12.1.46 ITE Fan Electricity Rate at Design Inlet Conditions [W]

#### 1.14.12.1.47 Space or Zone ITE Fan Electricity Energy at Design Inlet Conditions [J]

**1.14.12.1.48 ITE Fan Electricity Energy at Design Inlet Conditions [J]**

The electric power (or energy) input to the ITE cooling fan if the air inlet temperature were held at the design condition. May be used to calculate “IT efficiency”, the ratio of (IT energy consumed in the facility) / (IT energy that would have been consumed in the facility if the ITE were held at the reference temperature).

**1.14.12.1.49 Space or Zone ITE UPS Electricity Rate [W]****1.14.12.1.50 ITE UPS Electricity Rate [W]****1.14.12.1.51 Space or Zone ITE UPS Electricity Energy [J]****1.14.12.1.52 ITE UPS Electricity Energy [J]**

The net electric power (or energy) input to the ITE equipment UPS (total power input less power delivered to ITE). The ITE UPS Electricity Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. **Output:Meter** object).

**1.14.12.1.53 ITE Electricity Meters**

The ITE CPU Electricity Energy, ITE Fan Electricity Energy, and ITE UPS Electricity Energy are each included separately in the following Electricity meters, with their respective end-use subcategory:

```
Electricity:Facility
Electricity:Building
Electricity:Zone:<Zone Name>
Electricity:SpaceType:<Space Type Name>
InteriorEquipment:Electricity
InteriorEquipment:Electricity:Zone:<Zone Name>
InteriorEquipment:Electricity:SpaceType:<Space Type Name>
<End-Use Subcategory>:InteriorEquipment:Electricity
<End-Use Subcategory>:InteriorEquipment:Electricity:Zone:<Zone Name>
<End-Use Subcategory>:InteriorEquipment:Electricity:SpaceType:<Space Type Name>
```

**1.14.12.1.54 Space or Zone ITE UPS Heat Gain to Zone Rate [W]****1.14.12.1.55 ITE UPS Heat Gain to Zone Rate [W]****1.14.12.1.56 Space or Zone ITE UPS Heat Gain to Zone Energy [J]****1.14.12.1.57 ITE UPS Heat Gain to Zone Energy [J]**

The heat gain rate (or energy) to the zone from the UPS.

**1.14.12.1.58 Space or Zone ITE Total Heat Gain to Zone Rate [W]****1.14.12.1.59 ITE Total Heat Gain to Zone Rate [W]****1.14.12.1.60 Space or Zone ITE Total Heat Gain to Zone Energy [J]**

**1.14.12.1.61 ITE Total Heat Gain to Zone Energy [J]**

The heat gain rate (or energy) to the zone from the UPS and from the CPU and fans if the ITE. Air Inlet Connection Type is AdjustedSupply or ZoneAirNode. If RoomAirModel is selected, then only the heat gain from the UPS is added directly to the zone air heat balance, the heat gain from the CPU and fans will be added to the ITE air Outlet Room Air Model Node

**1.14.12.1.62 Space or Zone ITE Standard Density Air Volume Flow Rate [m<sup>3</sup>/s]****1.14.12.1.63 ITE Standard Density Air Volume Flow Rate [m<sup>3</sup>/s]**

Reports the average air volume flow rate through the ITE over the reporting interval. Standard density in EnergyPlus corresponds to 20°C dry bulb, dry air, and nominally adjusted for elevation.

**1.14.12.1.64 Space or Zone ITE Current Density Air Volume Flow Rate [m<sup>3</sup>/s]****1.14.12.1.65 ITE Current Density Air Volume Flow Rate [m<sup>3</sup>/s]**

Reports the average air volume flow rate through the ITE over the reporting interval, calculated using the current density at the air inlet node.

**1.14.12.1.66 Space or Zone ITE Air Mass Flow Rate [kg/s]****1.14.12.1.67 ITE Air Mass Flow Rate [kg/s]**

Reports the average air mass flow rate through the ITE over the reporting interval, calculated using the current density at the air inlet node.

**1.14.12.1.68 ITE Air Inlet Dry-Bulb Temperature [C]**

The dry-bulb temperature of the air entering the ITE.

**1.14.12.1.69 ITE Air Inlet Dewpoint Temperature [C]**

The dewpoint temperature of the air entering the ITE.

**1.14.12.1.70 ITE Air Inlet Relative Humidity [%]**

The dewpoint temperature of the air entering the ITE.

**1.14.12.1.71 ITE Air Outlet Dry-Bulb Temperature [C]**

The dry-bulb temperature of the air leaving the ITE.

**1.14.12.1.72 Space or Zone ITE Average Supply Heat Index []****1.14.12.1.73 ITE Supply Heat Index []**

The supply heat index (SHI) for this equipment. SHI is a dimensionless measure of recirculation of hot air into the cold air intake of the ITE. SHI = (Tin – Tsupply)/(Tout-Tsupply) where Tin is the dry-bulb temperature of the air entering the ITE, Tout is the dry-bulb temperature of the air leaving the ITE, and Tsupply is the dry-bulb temperature at the Supply Air Node. If a Supply Air Node Name is not specified for this object, then this output will not be reported.

**1.14.12.1.74 Space or Zone ITE Any Air Inlet Operating Range Exceeded Time [hr]**

**1.14.12.1.75 ITE Air Inlet Operating Range Exceeded Time [hr]**

Hours when the dry-bulb and/or dewpoint temperature of the air entering the ITE is outside the range specified by the ITE Environmental Class.

**1.14.12.1.76 Space or Zone ITE Any Air Inlet Dry-Bulb Temperature Above Operating Range Time [hr]**

1.14.12.1.77 ITE Air Inlet Dry-Bulb Temperature Above Operating Range Time [hr]

Hours when the dry-bulb temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

**1.14.12.1.78 ITE Air Inlet Dry-Bulb Temperature Difference Above Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dry-bulb temperature and the maximum allowable dry-bulb temperature specified by the ITE Environmental Class. Only positive values are reported. When the dry-bulb temperature of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.79 Space or Zone ITE Any Air Inlet Dry-Bulb Temperature Below Operating Range Time [hr]****1.14.12.1.80 ITE Air Inlet Dry-Bulb Temperature Below Operating Range Time [hr]**

Hours when the dry-bulb temperature of the air entering the ITE is below the range specified by the ITE Environmental Class.

**1.14.12.1.81 ITE Air Inlet Dry-Bulb Temperature Difference Below Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dry-bulb temperature and the minimum allowable dry-bulb temperature specified by the ITE Environmental Class. Only negative values are reported. When the dry-bulb temperature of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.82 Space or Zone ITE Any Air Inlet Dewpoint Temperature Above Operating Range Time [hr]**

1.14.12.1.83 ITE Air Inlet Dewpoint Temperature Above Operating Range Time [hr]

Hours when the dewpoint temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

**1.14.12.1.84 ITE Air Inlet Dewpoint Temperature Difference Above Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dewpoint temperature and the maximum allowable dewpoint temperature specified by the ITE Environmental Class. Only positive values are reported. When the dewpoint temperature of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.85 Space or Zone ITE Any Air Inlet Dewpoint Temperature Below Operating Range Time [hr]****1.14.12.1.86 ITE Air Inlet Dewpoint Temperature Below Operating Range Time [hr]**

Hours when the dewpoint temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

**1.14.12.1.87 ITE Air Inlet Dewpoint Temperature Difference Below Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dewpoint temperature and the minimum allowable dewpoint temperature specified by the ITE Environmental Class. Only negative values are reported. When the dewpoint temperature of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.88 Space or Zone ITE Any Air Inlet Relative Humidity Above Operating Range Time [hr]****1.14.12.1.89 ITE Air Inlet Relative Humidity Above Operating Range Time [hr]**

Hours when the relative humidity of the air entering the ITE is above the range specified by the ITE Environmental Class.

**1.14.12.1.90 ITE Air Inlet Relative Humidity Difference Above Operating Range [%]**

The temperature difference (in degrees DeltaC) between the air inlet relative humidity and the maximum allowable relative humidity specified by the ITE Environmental Class. Only positive values are reported. When the relative humidity of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.91 Space or Zone ITE Any Air Inlet Relative Humidity Below Operating Range Time [hr]****1.14.12.1.92 ITE Air Inlet Relative Humidity Below Operating Range Time [hr]**

Hours when the relative humidity of the air entering the ITE is below the range specified by the ITE Environmental Class.

**1.14.12.1.93 ITE Air Inlet Relative Humidity Difference Below Operating Range [%]**

The temperature difference (in degrees DeltaC) between the air inlet relative humidity and the minimum allowable relative humidity specified by the ITE Environmental Class. Only negative values are reported. When the relative humidity of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

**1.14.12.1.94 Zone ITE Adjusted Return Air Temperature [C]**

Return air temperature after adjustment by ITE objects.

### 1.14.13 ZoneBaseboard:OutdoorTemperatureControlled

This object specifies outside temperature-controlled (OTC) baseboard heating. The capacities (high and low) are specified in W at the temperatures specified. The schedule allows both capacities to change hourly on a proportional basis. This baseboard heater does not operate if the outdoor dry-bulb is above the high temperature limit. Between the high temperature and the low temperature, the capacity is interpolated (linear) between the high and the low capacity values. Below the low temperature, the capacity is set at the low capacity value. This allows the user to add baseboard heat to a perimeter zone starting at a prescribed temperature and then slowly increases this capacity to a max value.

**Example:**

Temperature High = 10 C	Capacity High = 100,000 W
Temperature Low = 0 C	Capacity Low = 500,000 W

Table 1.29: Outdoor Temperature Controlled Baseboard Heat Temperature vs. Capacity

Outdoor Dry-bulb(C)	Baseboard Output
> 10	0
10	100,000
8	180,000
6	260,000
4	340,000
2	420,000
0	500,000
$< 0$	500,000

#### 1.14.13.1 Inputs

##### 1.14.13.1.1 Field: Name

The name of the ZoneBaseboard:OutdoorTemperatureControlled object.

##### 1.14.13.1.2 Field: Zone or ZoneList or Space or SpaceList Name

This field applies this ZoneBaseboard:OutdoorTemperatureControlled object to one or more thermal zones or spaces in the building. The names of the actual baseboard heat objects may be concatenated as <Space Name> <ZoneBaseboard Object Name>. See [Specifying Applicable Zone\(s\) or Space\(s\)](#) for more details.

##### 1.14.13.1.3 Field: Schedule Name

This field is the name of the schedule that modifies the capacities (high and low) for baseboard heat equipment (see next four fields). The schedule values can be any positive number. The actual energy input for the baseboard equipment in a zone as defined by this statement depends on the actual outdoor temperature and where that temperature is in the range of Low Temperature to High Temperature..

#### 1.14.13.1.4 Field: Capacity at Low Temperature

This is the baseboard equipment capacity (Watts) at the low temperature limit. This is the maximum capacity of the baseboard equipment in full load operation. This field is autosizable.

#### 1.14.13.1.5 Field: Low Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is at or below the low temperature the baseboard heater operates at the low temperature capacity. This field is autosizable. The lowest design outdoor dry bulb temperature is chosen, if autosized.

#### 1.14.13.1.6 Field: Capacity at High Temperature

This is the baseboard equipment capacity (Watts) at the high temperature limit. This field is autosizable. The capacity at low temperature is prorated against the reference low and high temperature fields, if autosized.

#### 1.14.13.1.7 Field: High Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is greater than the high temperature the baseboard heater will not operate. This field is autosizable. If autosized, this is equal to the design zone heating setpoint temperature described below, so that the capacity at high temperature is zero.

#### 1.14.13.1.8 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by baseboard heat equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by the baseboard heat equipment to give the amount of long wavelength radiation gain to the zone.

#### 1.14.13.1.9 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Perimeter Baseboards”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table EAp2-4/5 Performance Rating Method Compliance. If this field is omitted or blank, the baseboard equipment will be assigned to the “General” end-use subcategory.

#### 1.14.13.1.10 Field: Design Zone Heating Setpoint

This is heating setpoint temperature in the zone where the unit serves. This is used to autosize high temperature and capacity at high temperature fields. The default value is 20°C.

An IDF example:

```
ZoneBaseboard:OutdoorTemperatureControlled,
  SPACE4-1 BBHeat 1,  !- Name
  SPACE4-1,          !- Zone Name
  EQUIP-1,           !- SCHEDULE Name
  1500,              !- Capacity at low temperature {W}
  0,                 !- Low Temperature {C}
  500,              !- Capacity at high temperature {W}

  Baseboard Heat,    !- End-Use Subcategory
  20;                !- Design Zone Heating Setpoint {C}
```

### 1.14.13.2 Outputs

ZoneBaseboard:OutdoorTemperatureControlled objects have output variables for individual objects and for zone totals. The following outputs are available:

- Zone,Average,Baseboard Electricity Rate [W]
- Zone,Sum,Baseboard Electricity Energy [J]
- Zone,Sum,Baseboard Radiant Heating Energy [J]
- Zone,Average,Baseboard Radiant Heating Rate [W]
- Zone,Sum,Baseboard Convective Heating Energy [J]
- Zone,Average,Baseboard Convective Heating Rate [W]
- Zone,Sum,Baseboard Total Heating Energy [J]
- Zone,Average,Baseboard Total Heating Rate [W]
- Zone,Average,Space Baseboard Electricity Rate [W]
- Zone,Sum,Space Baseboard Electricity Energy [J]
- Zone,Sum,Space Baseboard Radiant Heating Energy [J]
- Zone,Average,Space Baseboard Radiant Heating Rate [W]
- Zone,Sum,Space Baseboard Convective Heating Energy [J]
- Zone,Average,Space Baseboard Convective Heating Rate [W]
- Zone,Sum,Space Baseboard Total Heating Energy [J]
- Zone,Average,Space Baseboard Total Heating Rate [W]
- Zone,Average,Zone Baseboard Electricity Rate [W]
- Zone,Sum,Zone Baseboard Electricity Energy [J]
- Zone,Sum,Zone Baseboard Radiant Heating Energy [J]
- Zone,Average,Zone Baseboard Radiant Heating Rate [W]
- Zone,Sum,Zone Baseboard Convective Heating Energy [J]
- Zone,Average,Zone Baseboard Convective Heating Rate [W]
- Zone,Sum,Zone Baseboard Total Heating Energy [J]
- Zone,Average,Zone Baseboard Total Heating Rate [W]

#### 1.14.13.2.1 Baseboard Electricity Rate [W]

This field is the electric power for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts.

#### 1.14.13.2.2 Baseboard Electricity Energy [J]

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Total Heating Energy (above) in joules. This energy is included in the following meters:

```
Electricity:Facility
Electricity:Building
Electricity:Zone:<Zone Name>
Electricity:SpaceType:<Space Type Name>
InteriorEquipment:Electricity
InteriorEquipment:Electricity:Zone:<Zone Name>
InteriorEquipment:Electricity:SpaceType:<Space Type Name>
<End-Use Subcategory>:InteriorEquipment:Electricity
<End-Use Subcategory>:InteriorEquipment:Electricity:Zone:<Zone Name>
<End-Use Subcategory>:InteriorEquipment:Electricity:SpaceType:<Space Type Name>
```

#### 1.14.13.2.3 Baseboard Radiant Heating Rate [W]

**1.14.13.2.4 Baseboard Radiant Heating Energy [J]**

These output variables are the amount of radiant heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

**1.14.13.2.5 Baseboard Convective Heating Rate [W]****1.14.13.2.6 Baseboard Convective Heating Energy [J]**

These output variables are the amount of convective heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in input (1-FractionRadiant = FractionConvected). The convective heat gain is added to the zone air heat balance directly.

**1.14.13.2.7 Baseboard Total Heating Rate [W]****1.14.13.2.8 Baseboard Total Heating Energy [J]**

These output variables are the amount of heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

**1.14.13.2.9 Space or Zone Baseboard Electricity Rate [W]**

This field is the electric power for all ZoneBaseboard:OutdoorTemperatureControlled objects within the space or zone in Watts.

**1.14.13.2.10 Space or Zone Baseboard Electricity Energy [J]**

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Total Heating Energy (above) in joules.

**1.14.13.2.11 Space or Zone Baseboard Radiant Heating Rate [W]****1.14.13.2.12 Space or Zone Baseboard Radiant Heating Energy [J]**

These output variables are the amount of radiant heat gain for all ZoneBaseboard:OutdoorTemperatureControlled objects within the space or zone in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the space or zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

**1.14.13.2.13 Space or Zone Baseboard Convective Heating Rate [W]****1.14.13.2.14 Space or Zone Baseboard Convective Heating Energy [J]**

These output variables are the amount of convective heat gain for all ZoneBaseboard:OutdoorTemperatureControlled objects within the space or zone in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the space or zone and the “Fraction Radiant” specified in input (1-FractionRadiant = FractionConvected). The convective heat gain is added to the space or zone air heat balance directly.

**1.14.13.2.15 Space or Zone Baseboard Total Heating Rate [W]**

#### 1.14.13.2.16 Space or Zone Baseboard Total Heating Energy [J]

These output variables are the amount of heat gain for all ZoneBaseboard:OutdoorTemperature-Controlled objects within the space or zone in Watts (for rate) or Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

### 1.14.14 SwimmingPool:Indoor

The Indoor Swimming Pool object is used to describe the indoor swimming pools that are exposed to the internal environment. There are several rules that should be noted regarding the specification of an indoor pool in EnergyPlus. First, the pool is linked to a surface that must be a floor. The pool is assumed to cover the entire floor to which it is linked. If the pool only covers part of the floor in the actual building, then the user must break the floor up into multiple sections.

As pools attempt to achieve a particular water temperature and have a variety of heat losses, heating equipment is necessary to maintain the proper setpoint temperature. In EnergyPlus, the pool itself becomes part of the demand side of a plant loop with heating equipment on the supply side providing whatever heating is needed to maintain the desired temperature. This heating equipment as well as the loop connections must be entered separately and the input shown in this section only details what is needed to specify the pool itself.

There are a variety of rules that limit the application of indoor swimming pools in EnergyPlus. The following are a list of these rules:

- The pool must reference a valid surface in the input file. This surface must be a floor and cannot be other surface types like ceilings, walls, windows, etc.
- The pool cannot refer to a surface that is also a radiant system, ventilated slab, or another pool.
- The surface that the pool references must be modeled using conduction transfer functions (CTF).
- The pool cannot utilize movable insulation or have a heat source or sink associated with it (something used to model low temperature radiant systems).

The following information is useful for defining and modeling an indoor pool in EnergyPlus. For more information on the algorithm used for this model or details on some of the input parameters, please reference the indoor pool section of the EnergyPlus Engineering Reference document.

#### 1.14.14.1 Inputs

##### 1.14.14.1.1 Field: Name

This is a unique name associated with the indoor swimming pool.

##### 1.14.14.1.2 Field: Surface Name

This is the name of the surface (floor) where the pool is located. Pools are not allowed on any surfaces other than a floor. For more rules on surfaces that can be used for pools, please see the information in this section on indoor pools above.

##### 1.14.14.1.3 Field: Average Depth

This field is the average depth of the pool in meters. If the pool has variable depth, the average depth should be specified to achieve the proper volume of water in the pool.

#### 1.14.14.1.4 Field: Activity Factor Schedule Name

This field references a schedule that contains values for pool activity. This parameter can be varied using the schedule named here, and it has an impact on the amount of evaporation that will take place from the pool to the surrounding zone air. For example values of the activity factor and what impact it will have on the evaporation of water from the pool, please refer to the Indoor Swimming Pool section of the EnergyPlus Engineering Reference document. If left blank, the activity factor will be assumed to be unity. Note that the activity factor should not be set equal to an occupancy schedule since an activity factor of zero means that no evaporation will take place from the pool.

#### 1.14.14.1.5 Field: Make-up Water Supply Schedule Name

The scheduled named by this field establishes a cold water temperature [C] for the water that replaces the water which is lost from the pool due to evaporation. If blank, water temperatures are calculated by the [Site:WaterMainsTemperature](#) object. This field (even if blank) overrides the Cold Water Supply Temperature Schedule in all of the listed [WaterUse:Equipment](#) objects.

#### 1.14.14.1.6 Field: Cover Schedule Name

This schedule defines when the pool water cover is available and affects the evaporation, convection, and radiation rate calculations. A schedule value of 0.0 means that the pool is not covered. A schedule value of 1.0 means the pool is 100% covered. The pool may be fully covered, fully open (uncovered), or partially covered (a value between 0.0 and 1.0). The user also has the option to control the evaporation, convection, short-wavelength radiation, and long-wavelength radiation factors when the pool is covered. These terms are discussed in the next four fields.

#### 1.14.14.1.7 Field: Cover Evaporation Factor

This input field can optionally be used to modify the pool evaporation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates evaporation from the pool surface, 0 means the pool cover has no effect on evaporation, and fractions in between 0 and 1 result in a fractional reduction in evaporation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in evaporation from a fully uncovered pool is 25% or 0.25.

#### 1.14.14.1.8 Field: Cover Convection Factor

This input field can optionally be used to modify the pool convection rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates convection from the pool surface, 0 means the pool cover has no effect on convection, and fractions in between 0 and 1 result in a fractional reduction in convection by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in convection from a fully uncovered pool is 25% or 0.25.

#### 1.14.14.1.9 Field: Cover Short-Wavelength Radiation Factor

This input field can optionally be used to modify the pool short-wavelength radiation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates short-wavelength radiation from the pool surface, 0 means the pool cover has no effect on short-wavelength radiation, and fractions in between 0 and 1 result in a fractional reduction in short-wavelength radiation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in short-wavelength radiation from a fully uncovered pool is 25% or 0.25. Note that with radiation terms that

whatever portion of the short-wavelength radiation is blocked by the cover is transferred via convection to the surrounding zone air.

#### **1.14.14.1.10 Field: Cover Long-Wavelength Radiation Factor**

This input field can optionally be used to modify the pool long-wavelength radiation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates long-wavelength radiation from the pool surface, 0 means the pool cover has no effect on long-wavelength radiation, and fractions in between 0 and 1 result in a fractional reduction in long-wavelength radiation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in long-wavelength radiation from a fully uncovered pool is 25% or 0.25. Note that with radiation terms that whatever portion of the long-wavelength radiation is blocked by the cover is transferred via convection to the surrounding zone air.

#### **1.14.14.1.11 Field: Pool Water Inlet Node**

This input is the name of the node on the demand side of a plant loop that leads into the pool. From the standpoint of an EnergyPlus input file, the pool sits on a plant demand loop, and the pump and heater reside on the plant supply loop. The pool heater and pump must be defined by other existing EnergyPlus input.

#### **1.14.14.1.12 Field: Pool Water Outlet Node**

This input is the name of the node on the demand side of a plant loop that leads out of the pool. From the standpoint of an EnergyPlus input file, the pool sits on a plant demand loop, and the pump and heater reside on the plant supply loop. The pool heater and pump must be defined by other existing EnergyPlus input.

#### **1.14.14.1.13 Field: Pool Water Maximum Flow Rate**

This input is the maximum water volumetric flow rate in m<sup>3</sup>/s going between the pool and the water heating equipment. This along with the pool setpoint temperature and the heating plant equipment outlet temperature will establish the maximum heat addition to the pool. This flow rate to the pool will be varied in an attempt to reach the desired pool water setpoint temperature (see Setpoint Temperature Schedule below).

#### **1.14.14.1.14 Field: Pool Miscellaneous Equipment Power**

This input defines the power consumption rate of miscellaneous equipment such as the filtering and chlorination technology associated with the pool. The units for this input are in power consumption per flow rate of water through the pool from the heater or W/(m<sup>3</sup>/s). This field will be multiplied by the flow rate of water through the pool to determine the power consumption of this equipment. Any heat generated by this equipment is assumed to have no effect on the pool water itself.

#### **1.14.14.1.15 Field: Setpoint Temperature Schedule**

Pools attempt to maintain a particular water temperature. In EnergyPlus, this field defines the setpoint temperature for the desired pool water temperature. It is input as a schedule to allow the user to vary the pool setpoint temperature as desired. The equipment defined to provide heating for the pool will deliver the necessary hot water to the pool, up to the capacity of that equipment defined by other input by the user.

#### 1.14.14.1.16 Field: Maximum Number of People

This field defines the maximum occupancy of people actually in the pool and thus will be used with the next two inputs to determine how much heat people contribute to the pool heat balance. **People** who are not in the pool should be modeled separately using the standard **People** description for zones.

#### 1.14.14.1.17 Field: People Schedule

This field defines a schedule that establishes how many people are in the pool at any given time. The current value of this schedule is multiplied by the maximum number of people in the previous field determines how many people are currently in the pool.

#### 1.14.14.1.18 Field: People Heat Gain Schedule

This field defines the amount of heat given off by an average person in the pool in Watts. This field is a schedule so that this heat gain can be allowed to vary as the type of activity in a pool can vary greatly and thus the amount of heat gain per person also varies. This parameter times the number of people in the pool determines how much heat is added to the pool. All heat given off by people is added to the heat balance of the pool water.

An example of an indoor swimming pool definition is:

```
SwimmingPool:Indoor,

#### **1.14.14.2.1 Indoor Pool Makeup Water Rate [m<sup>3</sup>/s]**

The water consumption rate for the makeup water of indoor swimming pool.

#### **1.14.14.2.2 Indoor Pool Makeup Water Volume [m<sup>3</sup>]**

The water consumption for the makeup water of indoor swimming pool.

#### **1.14.14.2.3 Indoor Pool Makeup Water Temperature [C]**

The temperature of the makeup water of indoor swimming pool.

#### **1.14.14.2.4 Indoor Pool Water Temperature [C]**

The average calculated pool water temperature during the simulation at the time frequency requested.

#### **1.14.14.2.5 Indoor Pool Inlet Water Temperature [C]**

The temperature of the water being sent to the pool from the plant heating equipment.

#### **1.14.14.2.6 Indoor Pool Inlet Water Mass Flow Rate [kg/s]**

The mass flow rate of water being sent to the pool from the plant heating equipment. Typically this water is being passed through a heater and miscellaneous equipment.

#### **1.14.14.2.7 Indoor Pool Miscellaneous Equipment Power [W]**

The miscellaneous equipment power includes the power consumption of pool filter and chlorinator in Watts.

#### **1.14.14.2.8 Indoor Pool Miscellaneous Equipment Energy [J]**

The miscellaneous equipment power consumption includes the energy consumption of pool filter and chlorinator in Joules.

#### **1.14.14.2.9 Indoor Pool Water Heating Rate [W]**

This is the rate of heating provided by the plant loop to the pool in Watts.

#### **1.14.14.2.10 Indoor Pool Water Heating Energy [J]**

This is the amount of heating provided by the plant loop to the pool in Joules over the time step requested.

#### **1.14.14.2.11 Indoor Pool Radiant to Convection by Cover [W]**

The pool cover may block some or all of short- and long-wavelength radiation incident on the pool. To account for this and to not have the cover result in energy that is not accounted for by the model, the radiation that is blocked by the cover is converted to a convective gain (or loss) to/from the zone air. This output field reports this value.

**1.14.14.2.12 Indoor Pool Current Activity Factor []**

This is the current activity factor as defined by the user input schedule.

**1.14.14.2.13 Indoor Pool Current Cover Factor []**

This is the current cover factor as defined by the user input schedule.

**1.14.14.2.14 Indoor Pool Evaporative Heat Loss Rate [W]**

This is the rate of evaporative heat loss (latent) to the zone from the pool in Watts.

**1.14.14.2.15 Indoor Pool Evaporative Heat Loss Energy [J]**

This is the amount of evaporative heat loss (latent) to the zone from the pool in Joules over the time step requested.

**1.14.14.2.16 Indoor Pool Saturation Pressure at Pool Temperature [Pa]**

This is the saturation pressure of water vapor in air at the pool water temperature.

**1.14.14.2.17 Indoor Pool Partial Pressure of Water Vapor in Air [Pa]**

This is the partial pressure of water vapor in air at the current zone air conditions for dry bulb temperature and humidity ratio.

**1.14.14.2.18 Indoor Pool Current Cover Evaporation Factor []**

This is the current value of the cover evaporation factor that is used as a modifier for the actual evaporation. A value of zero means no evaporation will take place while a value of unity means the maximum allowed evaporation will take place. This value is based on the current cover condition as well as the user input for the cover evaporation factor.

**1.14.14.2.19 Indoor Pool Current Cover Convective Factor []**

This is the current value of the cover convective factor that is used as a modifier for the actual convection. A value of zero means the cover will block all convection while a value of unity means that the cover will not affect convection from the water surface at all. This value is based on the current cover condition as well as the user input for the cover convective factor.

**1.14.14.2.20 Indoor Pool Current Cover SW Radiation Factor []**

This is the current value of the cover short wavelength radiation factor that is used as a modifier for the actual short wavelength radiation. A value of zero means the cover will block all short wavelength radiation while a value of unity means that the cover will not affect short wavelength radiation from the water surface at all. This value is based on the current cover condition as well as the user input for the cover short wavelength radiation factor.

**1.14.14.2.21 Indoor Pool Current Cover LW Radiation Factor []**

This is the current value of the cover long wavelength radiation factor that is used as a modifier for the actual long wavelength radiation. A value of zero means the cover will block all long wavelength radiation while a value of unity means that the cover will not affect long wavelength radiation from the water surface at all. This value is based on the current cover condition as well as the user input for the cover long wavelength radiation factor.

## 1.14.15 ZoneContaminantSourceAndSink:CarbonDioxide

The ZoneContaminantSourceAndSink:CarbonDioxide object allows users to input carbon dioxide sources or sinks in a zone. Note that carbon dioxide generation within a zone can also be specified using **People** and **GasEquipment** objects. Multiple ZoneContaminantSourceAndSink:CarbonDioxide objects can be specified for the same zone.

### 1.14.15.1 Inputs

#### 1.14.15.1.1 Field: Name

The name of the ZoneContaminantSourceAndSink:CarbonDioxide object. The name for each ZoneContaminantSourceAndSink:CarbonDioxide object must be unique.

#### 1.14.15.1.2 Field: Zone Name

This field is the name of the zone (ref: **Zone**) and links a particular ZoneContaminantSourceAndSink:CarbonDioxide object to a thermal zone in the building.

#### 1.14.15.1.3 Field: Design Generation Rate

This field denotes the design carbon dioxide generation rate ( $\text{m}^3/\text{s}$ ). The design value is modified by the schedule fraction (see Field: Schedule Name). The resulting volumetric generation rate is converted to mass generation rate using the current zone indoor air density at each time step. The rate can be either positive or negative. A positive value represents a source rate ( $\text{CO}_2$  addition to the zone air) and a negative value represents a sink rate ( $\text{CO}_2$  removal from the zone air).

When the mass design generation rate is available, a conversion is required to meet input requirement with volumetric flow rate. This can be accomplished by the mass flow rate divided by the density of carbon dioxide.

#### 1.14.15.1.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedules) that modifies the design carbon dioxide generation rate (see previous field). The schedule values can be any positive number between 0.0 and 1.0. For each simulation time step, the actual  $\text{CO}_2$  generation rate in a zone is the product of the Design Generation Rate field (above) and the value specified by this schedule.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:CarbonDioxide,
  NORTH_ZONE CO2,          !- Name
  NORTH_ZONE,              !- Zone Name
  1.e-6,                  !- Design Generation Rate {m3/s}
  CO2 Source Schedule;   !- Schedule Name
```

### 1.14.15.2 Outputs

HVAC,Average, Contaminant Source or Sink CO2 Gain Volume Flow Rate [m <sup>3</sup> /s]
HVAC,Average, Zone Contaminant Source or Sink CO2 Gain Volume Flow Rate [m <sup>3</sup> /s]

#### 1.14.15.2.1 Contaminant Source or Sink CO2 Gain Volume Flow Rate [m<sup>3</sup>/s]

This output is the net carbon dioxide internal gain/loss in  $\text{m}^3/\text{s}$  for an individual ZoneContaminantSourceAndSink:CarbonDioxide object.

### 1.14.15.2.2 Zone Contaminant Source or Sink CO<sub>2</sub> Gain Volume Flow Rate [m<sup>3</sup>/s]

This output is the net carbon dioxide internal gain/loss in m<sup>3</sup>/s for all ZoneContaminantSourceAndSink:CarbonDio objects in a zone.

## 1.14.16 ZoneContaminantSourceAndSink:Generic:Constant

The ZoneContaminantSourceAndSink:Generic:Constant object specifies the generic contaminant generation rate and removal rate coefficient in a zone. The associated fraction schedules are required for allowing users to change the magnitude of sources and sinks. The object is equivalent to the combination of the constant coefficient model and the burst source model defined in the sources and sinks element types of CONTAM 3.0. The basic equation used to calculate generic contaminant source and sink for the constant model is given below:

$$S_f(t) = G_f(t) * F_G - R_f(t)C_f(t) * 1.0E - 6 * F_R \quad (1.31)$$

where

$S_f$  = Contaminant generic contaminant source strength [m<sup>3</sup>/s]

$G_f$  = Generic contaminant generation rate [m<sup>3</sup>/s]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$R_f$  = Generic contaminant effective removal rate [m<sup>3</sup>/s]

$F_R$  = Fraction value from the sink fraction schedule at a given time [dimensionless]

$C_f$  = Generic contaminant concentration value at a given previous time step [ppm]

### 1.14.16.1 Inputs

#### 1.14.16.1.1 Field: Name

This field represents a unique identifying name.

#### 1.14.16.1.2 Field: Zone Name

This field signifies the Name of the zone with constant generic contaminant source and sink.

#### 1.14.16.1.3 Field: Design Generation Rate

This field denotes the full generic contaminant design generation rate (m<sup>3</sup>/s). The design generation rate is the maximum amount of generic contaminant expected at design conditions. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

When the mass generation rate is available, the rate must be converted to a volume flow rate. Use the mass flow rate divided by the vapor density of the generic contaminant.

#### 1.14.16.1.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $G_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation.

#### 1.14.16.1.5 Field: Design Removal Coefficient

This field denotes the full generic contaminant design removal coefficient (m<sup>3</sup>/s). The design removal rate is the maximum amount of generic contaminant expected at design conditions times the generic contaminant concentration in the same zone. The design value is modified by the schedule fraction (see Field:Removal Schedule Name).

### 1.14.16.1.6 Field: Removal Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $R_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:Generic:Constant,
  NORTH ZONE GC,          !- Name
  NORTH ZONE,             !- Zone Name
  1.0E-6,                !- Design Generation Rate {m3/s}
  GC Source Schedule,    !- Generation Schedule Name
  1.0E-7,                !- Design Removal Coefficient {m3/s}
  GC Removal Schedule;  !- Removal Schedule Name
```

---

### 1.14.16.2 Outputs

When a ZoneContaminantSourceAndSink:Generic:Constant object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Constant Source Generation Volume Flow Rate [m<sup>3</sup>/s]

### 1.14.16.2.1 Generic Air Contaminant Constant Source Generation Volume Flow Rate [m<sup>3</sup>/s]

This output is the average generic contaminant generation rate from each ZoneContaminantSourceAndSink:Generic object. The generation rate is a sum of generation and removal rates. The zone air generic contaminant level at the previous zone time step is used in the removal rate calculation.

## 1.14.17 SurfaceContaminantSourceAndSink:Generic:PressureDriven

The SurfaceContaminantSourceAndSink:Generic:PressureDriven object specifies the generic contaminant generation rate coefficient, which is used to calculate the generation rate due to the pressure difference across the surface. The object is equivalent to the pressure driven model defined in the sources and sinks element types of CONTAM 3.0. This object assumes to work with the AirflowNetwork model. The surface has to be defined in the AirflowNetwork:Multizone:Surface. Although the model is designed to be applied to radon and soil gas entry, it is expanded to be applied to all contaminant transport, including generic contaminant. However, it should be used in caution. The basic equation used to calculate generic contaminant source for the pressure driven constant model is provided below:

$$S_f(t) = H_f(t) * F_G * (P_j - P_i)^n \quad (1.32)$$

where

$S_f$  = Generic contaminant source strength [m<sup>3</sup>/s]

$H_f$  = Generic contaminant generation rate coefficient [m<sup>3</sup>/s]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$n$  = Flow power exponent

$P_i$  = Zone pressure [Pa]

$P_j$  = Pressure in an adjacent zone for a interior surface or outdoor for an exterior surface [Pa]

### 1.14.17.1 Inputs

#### 1.14.17.1.1 Field: Name

The field signifies the unique identifying name.

### 1.14.17.1.2 Field: Surface Name

This field represents the name of the surface as a generic contaminant source using the pressure driven model.

### 1.14.17.1.3 Field: Design Generation Rate Coefficient

This field denotes the generic contaminant design generation coefficient ( $\text{m}^3/\text{s}$ ). The design generation rate is the maximum amount of generic contaminant expected at design conditions times the pressure difference with a power exponent across a surface. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

### 1.14.17.1.4 Field: Generation Exponent

This field denotes the flow power exponent,\*  $n^*$ , in the contaminant source equation. The valid range is 0.0 to 1.0,

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:Generic:PressureDriven,
  WEST ZONE GC BLD,      !- Name
  Zn001:Wall1001,        !- Surface Name
  1.0E-6,                !- Design Generation Rate Coefficient {m3/s}
  GC Source Schedule,    !- Generation Schedule Name
  0.5;                  !- Generation Exponent
```

---

## 1.14.17.2 Outputs

When a SurfaceContaminantSourceAndSink:Generic:PressureDriven object is specified, the following output variables are available:

- ZONE,Average,Generic Air Contaminant Pressure Driven Generation Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

### 1.14.17.2.1 Generic Air Contaminant Pressure Driven Generation Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:Generic:PressureDriven object.

## 1.14.18 ZoneContaminantSourceAndSink:Generic:CutoffModel

The ZoneContaminantSourceAndSink:Generic contaminant:CutoffModel object specifies the generic contaminant generation rate based on the cutoff concentration model. The basic equation used to calculate generic contaminant source for the pressure driven constant model is given below:

$$S_f(t) = \begin{cases} G_f(t) * F_G * \left(1 - \frac{C_f(t)}{C_{cutoff}}\right) & C_f < C_{cutoff} \\ 0 & C_f \geq C_{cutoff} \end{cases} \quad (1.33)$$

where

$S_f$  = Generic contaminant source strength [ $\text{m}^3/\text{s}$ ]

$G_f$  = Generic contaminant generation rate [ $\text{m}^3/\text{s}$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$C_{cutoff}$  = Cutoff concentration at which emission ceases [ppm]

$C_f$  = Generic contaminant concentration value at a given previous time step [ppm]

### 1.14.18.1 Inputs

#### 1.14.18.1.1 Field: Name

The field signifies the unique identifying name.

#### 1.14.18.1.2 Field: Zone Name

This field represents the name of the zone with generic contaminant source and sink using the cutoff model.

#### 1.14.18.1.3 Field: Design Generation Rate Coefficient

This field denotes the full generic contaminant design generation rate ( $\text{m}^3/\text{s}$ ). The design generation rate is the maximum amount of generic contaminant expected at design conditions. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

When the mass generation rate is available, the rate must be converted to a volume flow rate. Use the mass flow rate divided by the vapor density of the generic contaminant.

#### 1.14.18.1.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $G_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation.

#### 1.14.18.1.5 Field: Cutoff Generic Contaminant at which Emission Ceases

This field is the generic contaminant cutoff concentration level where the source ceases its emission.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:Generic:CutoffModel,
  NORTH ZONE GC CutoffModel,           !- Name
  NORTH ZONE,                         !- Zone Name
  1.0E-5,                            !- Design Generation Rate Coefficient {m3/s}
  GC Source Schedule,                !- Schedule Name
  100000;                            !- Cutoff Generic Contaminant at which Emission Ceases {ppm}
```

---

### 1.14.18.2 Outputs

When a ZoneContaminantSourceAndSink:Generic:CutoffModel object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Cutoff Model Generation Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

#### 1.14.18.2.1 Generic Air Contaminant Cutoff Model Generation Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

This output is the average generic contaminant generation rate from each SurfaceContaminantSource-AndSink:Generic:CutoffModel object.

### 1.14.19 ZoneContaminantSourceAndSink:Generic:DecaySource

The ZoneContaminantSourceAndSink:Generic:DecaySource object specifies the generic contaminant generation rate based on the decay source model. The basic equation used to calculate generic contaminant source for the decay source model is given below:

$$S_f(t) = G_f(t)F_G \exp(-t/t_c) \quad (1.34)$$

where

$S_f$  = Generic contaminant source strength [ $\text{m}^3/\text{s}$ ]

$G_f$  = Initial generic contaminant generation rate [ $\text{m}^3/\text{s}$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$t$  = Time since the start of emission [second]

$t_c$  = Decay time constant [second]

### 1.14.19.1 Inputs

#### 1.14.19.1.1 Field: Name

This field is the unique identifying name.

#### 1.14.19.1.2 Field: Zone Name

This field represents the name of the zone with a generic contaminant decaying source.

#### 1.14.19.1.3 Field: Initial Emission Rate

This field denotes the initial generic contaminant design emission rate ( $\text{m}^3/\text{s}$ ). The generation is controlled by a schedule, as defined in the next field. Generic contaminant emission begins when the schedule changes from a zero to a non-zero value (between zero and one). The initial emission rate is equal to the schedule value times the initial generation rate. A single schedule may be used to initiate several emissions at different times.(see Field:Generation Schedule Name).

#### 1.14.19.1.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design emission rate ( $G_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation. When the value is equal to 1, the generation rate is used and time is reset to zero. When the value is equal to zero, the schedule value is ignored in the equation.

#### 1.14.19.1.5 Field: Decay Time Constant

This field is the time at which the generation rate reaches 0.37 of the original rate.

Note: The variable  $t$ , time since the start of emission, will be reset to zero, when a new run period starts, or the generation schedule value is equal to zero.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:Generic:DecaySource,
  WEST ZONE GC DecaySource, !- Name
  WEST ZONE,           !- Zone Name
  1.0E-5,              !- Initial Emission Rate {m3/s}
  GC Source Schedule, !- Schedule Name
  100000;              !- Delay Time Constant {s}
```

### 1.14.19.2 Outputs

When a ZoneContaminantSourceAndSink:Generic:DecaySource object is specified, the following output variables are available:

- Zone,Average,Generic Air Contaminant Decay Model Generation Volume Flow Rate [ $\text{m}^3/\text{s}$ ]
- Zone,Average,Generic Air Contaminant Decay Model Generation Emission Start Elapsed Time [s]

### 1.14.19.2.1 Generic Air Contaminant Decay Model Generation Volume Flow Rate [m<sup>3</sup>/s]

This output is the average generic contaminant decay rate from each SurfaceContaminantSourceAndSink:Generic:DecaySource object.

### 1.14.19.2.2 Generic Air Contaminant Decay Model Generation Emission Start Elapsed Time [s]

This output is the decay time since the start of emission. The start time is either at the beginning of each run period, including design day simulations, or the time when the egenration schedule value is zero.

## 1.14.20 SurfaceContaminantSourceAndSink:Generic:BoundaryLayer-Diffusion

The SurfaceContaminantSourceAndSink:Generic:BoundaryLayerDiffusion object specifies the generic contaminant generation rate from surface diffusion. The object is equivalent to the boundary layer diffusion model driven model defined in the sources and sinks element types of CONTAM 3.0.

The boundary layer diffusion controlled reversible sink/source model with a linear sorption isotherm follows the descriptions presented in [Axley 1991]. The boundary layer refers to the region above the surface of a material through which a concentration gradient exists between the near-surface concentration and the air-phase concentration. The rate at which a contaminant is transferred onto a surface (sink) is defined as:

$$S_f = h * \rho * A \left( C_f - \frac{C_s}{k} \right) * 1.0E - 6 \quad (1.35)$$

where

$h$  = Average film mass transfer coefficient over the sink [m/s]

$\rho$  = Film density of air [kg/m<sup>3</sup>]

$A$  = Surface area of the adsorbent [m<sup>2</sup>]

$C_f$  = Concentration in the air at the previous time step [ppm]

$C_s$  = Concentration in the adsorbent [ppm]

$k$  = Henry adsorption constant or partition coefficient [dimensionless]

### 1.14.20.1 Inputs

#### 1.14.20.1.1 Field: Name

This field signifies a unique identifying name.

#### 1.14.20.1.2 Field: Surface Name

This field denotes the name of the surface as a generic contaminant reversible source or sink using the boundary layer diffusion model.

#### 1.14.20.1.3 Field: Mass Transfer Coefficient

This field specifies the average mass transfer coefficient of the contaminant generic contaminant within the boundary layer (or film) above the surface of the adsorbent.

#### 1.14.20.1.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the mass transfer coefficient with the value between 0.0 and 1.0.

### 1.14.20.1.5 Field: Henry Adsorption Constant or Partition Coefficient

This field denotes the generic contaminant Henry partition coefficient in the units of dimensionless. The coefficient relates the concentration of the contaminant generic contaminant in the bulk-air to that at the surface of the adsorption material.

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:Generic:BoundaryLayerDiffusion,
  WEST ZONE GC BLD,      !- Name
  Zn001:Wall1001,        !- Surface Name
  1.0E-2,                !- Mass Transfer Coefficient {m/s}
  GC Source Schedule,   !- Schedule Name
  2.0;                  !- Henry adsorption constant or partition coefficient
```

---

### 1.14.20.2 Outputs

When a SurfaceContaminantSourceAndSink:Generic:BoundaryLayerDiffusion object is specified, the following output variables are available:

- ZONE,Average, Generic Air Contaminant Boundary Layer Diffusion Generation Volume Flow Rate [m<sup>3</sup>/s]
- ZONE,Average, Generic Air Contaminant Boundary Layer Diffusion Inside Face Concentration [ppm]

#### 1.14.20.2.1 Generic Air Contaminant Boundary Layer Diffusion Generation Volume Flow Rate [m<sup>3</sup>/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:Generic:BoundaryLayerDiffusion object.

#### 1.14.20.2.2 Generic Air Contaminant Boundary Layer Diffusion Inside Face Concentration [ppm]

This output is the average generic contaminant level at the interior surface.

### 1.14.21 SurfaceContaminantSourceAndSink:Generic:Deposition-VelocitySink

The SurfaceContaminantSourceAndSink:Generic:DepositionVelocitySink object specifies the generic contaminant removal rate from a surface. The object is equivalent to the deposition velocity sink model defined in CONTAM 3.0 sources and sinks element types.

The deposition velocity model provides for the input of a sink's characteristic in the familiar term of deposition velocity. The removal stops when the sink concentration level is higher than the zone air concentration level. The deposition velocity model equation is:

$$S_f(t) = \nu_d A_s m * C_f(t) * 1.0E - 6 * F_R \quad (1.36)$$

where

$S_f(t)$  = Removal rate at time t [m<sup>3</sup>/s]

$\nu_d$  = Deposition velocity [m/s]

$A_s$  = Deposition surface area [m<sup>2</sup>]

$m$  = Element multiplier [dimensionless]

$C_f(t)$  = Concentration of contaminant generic contaminant at the previous time step [ppm]

$F_R$  = Schedule or control signal value at time t [-]

### 1.14.21.1 Inputs

#### 1.14.21.1.1 Field: Name

This field denotes a unique identifying name.

#### 1.14.21.1.2 Field: Surface Name

This field represents the name of the surface as a generic contaminant sink using the deposition velocity sink model.

#### 1.14.21.1.3 Field: Deposition Velocity

This field specifies the deposition velocity to the surface of the adsorbent in the units of m/s.

#### 1.14.21.1.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design removal rate ( $S_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:Generic:DepositionVelocitySink,
  EAST ZONE GC DVS,      !- Name
  Zn002:Wall1001,        !- Surface Name
  1.0E-3,                !- Deposition Velocity {m/s}
  GC Source Schedule;   !- Schedule Name
```

---

### 1.14.21.2 Outputs

The following output variables are available when the SurfaceContaminantSourceAndSink:Generic:DepositionVelocitySink object is specified.

- ZONE,Average, Generic Air Contaminant Deposition Velocity Removal Volume Flow Rate [m<sup>3</sup>/s]

#### 1.14.21.2.1 Generic Air Contaminant Deposition Velocity Removal Volume Flow Rate [m<sup>3</sup>/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:Generic:DepositionVelocitySink object.

## 1.14.22 ZoneContaminantSourceAndSink:Generic:DepositionRateSink

The ZoneContaminantSourceAndSink:Generic:DepositionRateSink object specifies the generic contaminant removal rate from a zone. The object is equivalent to the deposition rate sink model defined in CONTAM 3.0 sources and sinks element types.

The deposition rate model provides for the input of a sink's characteristic in the familiar term of deposition rate in a zone. The removal stops when the sink concentration level is higher than the zone air concentration level. The deposition rate model equation is:

$$S_f(t) = k_d V_z * C_f(t) * 1.0E - 6 * F_R m \quad (1.37)$$

Where

$S_f(t)$  = Removal rate at time t [m<sup>3</sup>/s]

$k_d$  = Deposition rate [1/T]

$V_z$  = Zone volume [m<sup>3</sup>]

$m$  = Element multiplier [dimensionless]

$C_f(t)$  = Concentration of generic contaminant at the previous time step [ppm]

$F_R$  = Schedule or control signal value at time t [dimensionless]

### 1.14.22.1 Inputs

#### 1.14.22.1.1 Field: Name

This field denotes a unique identifying name.

#### 1.14.22.1.2 Field: Zone Name

This field represents the name of the zone as a generic contaminant sink using the deposition rate sink model.

#### 1.14.22.1.3 Field: Deposition Rate

This field specifies the deposition rate to the zone in the units of 1/s.

#### 1.14.22.1.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design removal rate ( $S_f$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:Generic:DepositionRateSink,
  NORTH ZONE GC DRS,      !- Name
  NORTH ZONE,              !- Zone Name
  1.0E-5,                  !- Deposition Rate {m3/s}
  GC Source Schedule;     !- Schedule Name
```

### 1.14.22.2 Outputs

When the ZoneContaminantSourceAndSink:Generic:DepositionRateSink object is specified, the following output variables are available:

- ZONE,Average, Generic Air Contaminant Deposition Rate Removal Volume Flow Rate [m<sup>3</sup>/s]

#### 1.14.22.2.1 Generic Air Contaminant Deposition Rate Removal Volume Flow Rate [m<sup>3</sup>/s]

This output is the average generic contaminant generation rate from each ZoneContaminantSource-AndSink:Generic:DepositionRateSink object.

## 1.15 Group – Daylighting

Daylighting can be invoked in EnergyPlus primarily by the use of the objects: **Daylighting:Controls** and **Daylighting:ReferencePoint**. Other objects related to daylighting are **Daylighting:DElight:ComplexFenestratOutput:IlluminanceMap**, and **OutputControl:IlluminanceMap:Style**. These are described in the following object descriptions.

Note that two different methodologies are used in the **Daylighting:Controls** object (SplitFlux and DElight) and may be intermixed in a single IDF but may not be used in the same zone.

## 1.15.1 Daylighting:Controls

When this object is used, daylighting illuminance levels are calculated and then used to determine how much the electric lighting can be reduced. The daylight illuminance level in a zone depends on many factors, including sky condition; sun position; calculation point; location, size, and glass transmittance of windows; window shading devices; and reflectance of interior surfaces. Reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled and type of lighting control. Two different methods of computing the daylighting illuminance and subsequent lighting reduction called SplitFlux and DLight. After the object description below are sections that describe the two methodologies in more detail.

### 1.15.1.1 Inputs

#### 1.15.1.1.1 Field: Name

The name of the Daylighting:Controls object.

#### 1.15.1.1.2 Field: Zone or Space Name

The name of the **Zone** or **Space** to which the following daylighting-related input applies. If a zone name is specified, the zone must lie completely within a single solar enclosure.

#### 1.15.1.1.3 Field: Daylighting Method

The Daylighting Method field can be set to either of the following: SplitFlux or DLight. Different Zones can have different settings in the same file but in a single zone only one method should be used at a time. Guidelines for using the SplitFlux method and additional details on the DLight method are shown in following sections.

#### 1.15.1.1.4 Field: Availability Schedule Name

This alpha field is optional and may be used to define the name of a schedule that denotes whether or not the control is available to operate during a given time period. If the schedule value is greater than zero, then the controls will be available to operate for that time period. If the schedule value is zero or less, then the controls will not be available. If this field is left blank, the controls will be always available. For example, this can be useful for scheduling the daylighting controls off during design days so that the daylighting controls do not affect lighting power during sizing.

#### 1.15.1.1.5 Field: Lighting Control Type

The type of overhead electric lighting control. All reference points specified are assumed to have this type of control.

For Lighting Control Type set to Continuous, the overhead lights dim continuously and linearly from (maximum electric power, maximum light output) to (minimum electric power, minimum light output) as the daylight illuminance increases. The lights stay on at the minimum point with further increase in the daylight illuminance.

For Lighting Control Type set to Stepped, the electric power input and light output vary in discrete, equally spaced steps. The number of steps is given by Number of Steps (Excluding Off) of Stepped Control. For example, if Number of Steps = 3 and Illuminance Setpoint = 600, then the following table shows the fraction of the lights that are on vs. daylight illuminance.

Table 1.30: Example of a Stepped Lighting Control System with Three Steps

Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	2/3
400-600	1/3
600 and above	0.0

Lighting Control Type set to ContinuousOff is the same similar to Lighting Control Type set to Continuous except that the lights switch off completely when the minimum dimming point is reached.

#### 1.15.1.1.6 Field: Minimum Input Power Fraction for Continuous Dimming Control

For Lighting Control Type set to Continuous, the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power (see figure, below). For Lighting Control Type set to ContinuousOff, this is the power fraction reached just before the lights switch off completely.

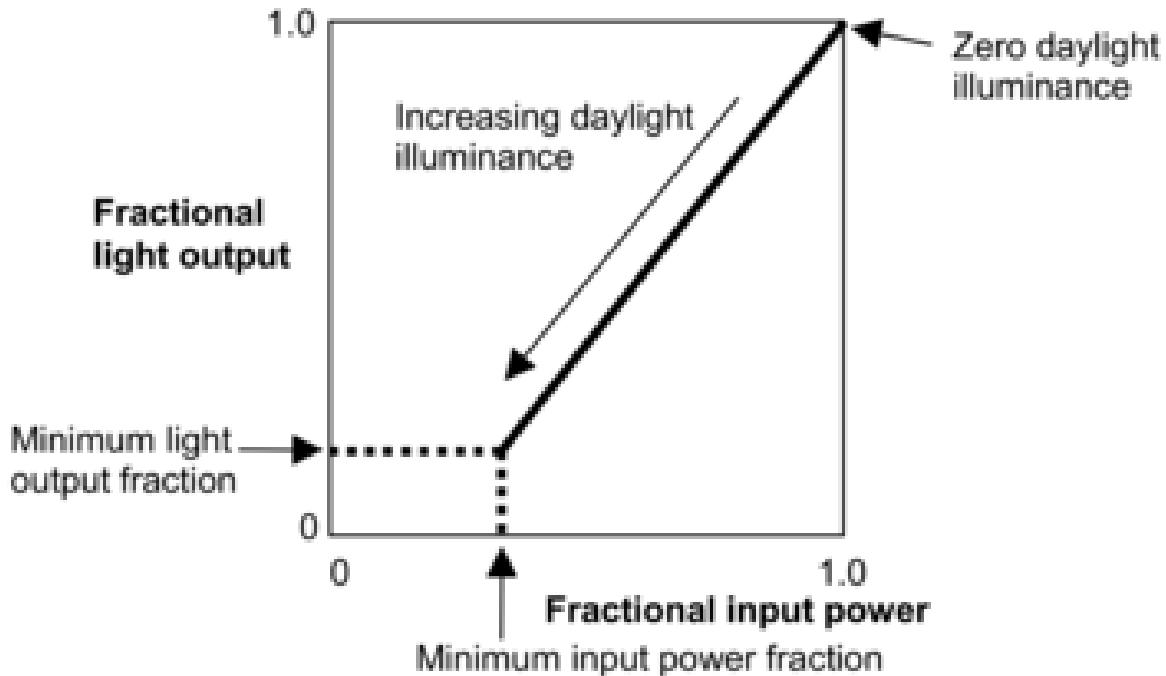

Figure 1.73: Illustration of continuous dimming relationship

The figure shows the relationship between electric light output and electrical input.

#### 1.15.1.1.7 Field: Minimum Light Output Fraction for Continuous Dimming Control

For Lighting Control Type set to Continuous, the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output (see figure). This is the fractional light output

that the system produces at minimum input power. For Lighting Control Type set to ContinuousOff, this is the light output fraction reached just before the lights switch off completely.

#### 1.15.1.1.8 Field: Number of Stepped Control Steps

The number of steps, excluding off, in a stepped lighting control system (see figure, below). Required and must be  $>0$  if Lighting Control Type is set to Stepped. The steps are assumed to be equally spaced.

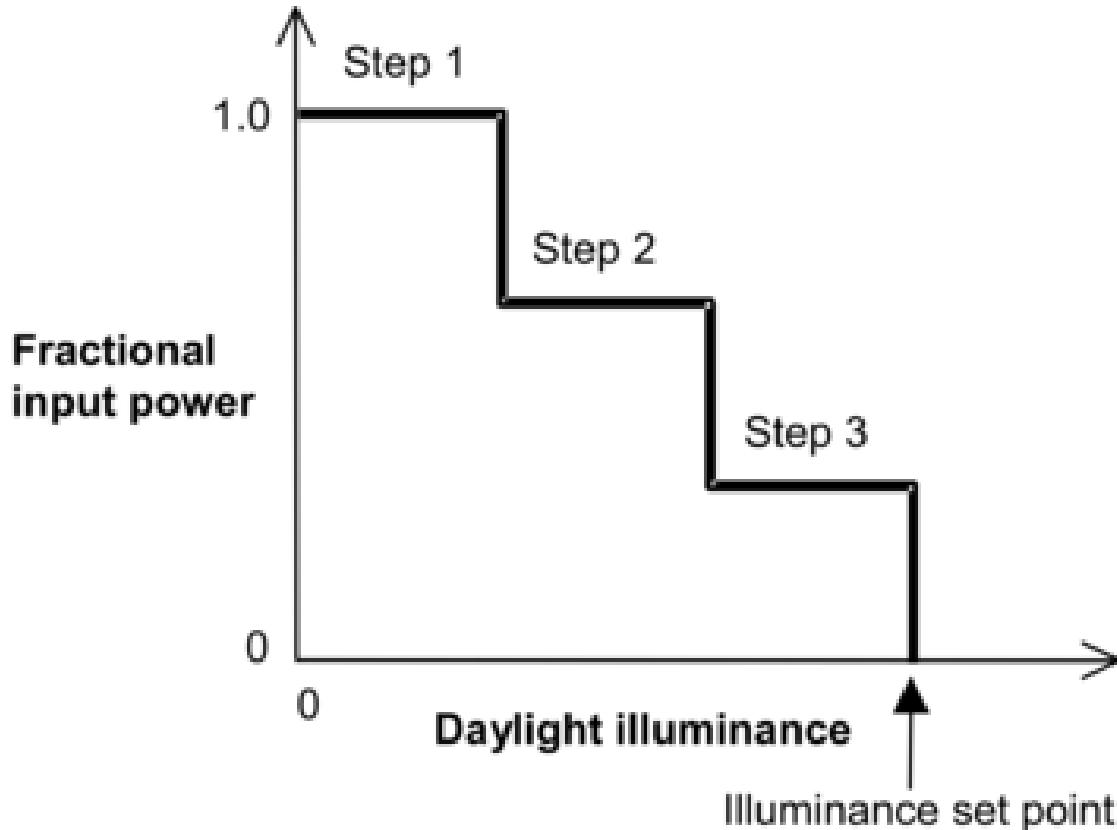

Figure 1.74: Stepped lighting control with Number of Steps = 3.

#### 1.15.1.1.9 Field: Probability Lighting will be Reset When Needed in Manual Stepped Control

May be specified if a stepped lighting control system (Lighting Control Type set to Stepped) is manually operated, such as in a simple, one-step (on-off) system. Gives the probability the occupants of a daylit zone will set the electric lights to the correct level to obtain the required illuminance. The rest of the time the lights are assumed to be set one step too high. For example, consider an on-off lighting system (Number of Steps = 1) with a set point of 600 lux and 0.7 reset probability. Then, when daylighting exceeds 600 lux, the electric lights will be off 70% of the time and on 30% of the time.

#### 1.15.1.1.10 Field: Glare Calculation Daylighting Reference Point Name

The **Daylighting:ReferencePoint** name should be specified that is used for determining the glare. Only one reference point is used to calculate the glare. This input is only used in when the Daylighting Method is set to SplitFlux. This input is ignored when Daylighting Method is set to DElight.

### 1.15.1.1.11 Field: Glare Calculation Azimuth Angle of View Direction Clockwise from Zone y-Axis

Daylight glare from a window depends on occupant view direction. It is highest when you look directly at a window and decreases as you look away from a window. This field specifies the view direction for calculating glare. It is the angle, measured clockwise in the horizontal plane, between the zone y-axis and the occupant view direction. This input is only used in when the Daylighting Method is set to SplitFlux. This input is ignored when Daylighting Method is set to DElight.

### 1.15.1.1.12 Field: Maximum Allowable Discomfort Glare Index

If a daylit zone has windows with shading devices (except exterior screens), the shades will be deployed if the daylight glare at **Daylighting:ReferencePoint** specified in the Glare Calculation Daylighting Reference Point Name field exceeds the value of this field. To get this type of glare control you have to specify Trigger = Glare, GlareOrSolarOnWindow, GlareOrHorizontalSolar, GlareOrOutsideAirTemp, GlareOrZoneAirTemp or GlareOrZoneLoad in **WindowShadingControl** for one or more windows in the zone (see **WindowShadingControl**). This input is only used in when the Daylighting Method is set to SplitFlux. This input is ignored when Daylighting Method is set to DElight.

If a zone has two or more windows with glare control, the shading devices will be deployed one by one in the order in which the windows are input until the glare level at each reference point falls below Maximum Allowable Discomfort Glare Index or is as close as possible to it.

The following table gives recommended values of Maximum Allowable Discomfort Glare Index.

Table 1.31: Recommended Values of Maximum Allowable Discomfort Glare Index (DGI)

Activity or Zone Type	Maximum Allowable DGI
Art Galleries	16
Factories: Rough work	28
Factories: Engine assembly	26
Factories: Fine assembly	24
Factories: Instrument assembly	22
Hospital wards	18
Laboratories	22
Museums	20
Offices	22
School classrooms	20

### 1.15.1.1.13 Field: DElight Gridding Resolution

The maximum surface area for nodes in gridding (subdividing) all surfaces in the zone when Daylighting Method is set to DElight. All reflective and transmitting surfaces will be subdivided into approximately square nodes that do not exceed this maximum. Higher resolution subdivisions require greater calculation times, but generally produce more accurate results. This same gridding resolution is also used to subdivide any Complex Fenestration System surfaces. It is advisable to perform at least one simulation of new input using a small gridding resolution such as 0.1m<sup>2</sup> to compare these results against simulation runs at lower resolution (i.e., higher maximum area nodal grids) to get a sense of possible levels of error. This input is only used in when the Daylighting Method is set to DElight. This input is ignored when Daylighting Method is set to SplitFlux.

#### 1.15.1.1.14 Field Set (reference point name, fraction controlled, illuminance setpoint)

This set of fields is used together and can be repeated an unlimited number of times to specify some of the name of the reference point, the fraction of the zone lighting controlled by that reference point and the illuminance setpoint that should be applied for daylighting control at that reference point.

##### 1.15.1.1.15 Field: Daylighting Reference Point Name <x>

The [Daylighting:ReferencePoint](#) name should be specified that is used for determining the daylighting control sensor location.

##### 1.15.1.1.16 Field: Fraction of Lights Controlled by Reference Point <x>

The fraction of the zone or space's electric lighting is controlled by the daylight illuminance at the named [Daylighting:ReferencePoint](#). If the sum of the fractions are less than 1.0, the remaining portion is assumed to have no lighting control.

##### 1.15.1.1.17 Field: Illuminance Setpoint at Reference Point <x>

The desired lighting level (in lux) at the named [Daylighting:ReferencePoint](#). This is the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power. Recommended values depend on type of activity; they may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America. A typical value for general office work (excluding computer terminals) is 500 lux.

## 1.15.2 Daylighting:ReferencePoint

This object is referenced by [Daylighting:Controls](#) to identify the reference point coordinates for each sensor. The reference points in the zone are where horizontal daylighting illuminance will be calculated. It is assumed that the photocells that control the overhead electric lighting respond to the light levels at the specified coordinates. Reference points are given in coordinates specified in the [GlobalGeometryRules](#) object Daylighting Reference Point CoordinateSystem field.

When the DElight Daylighting Method is used, there may be up to a maximum of 100 reference points for each zone. Each Reference Point that is input does NOT need to be included in the control of the electric lighting system within the zone. This is determined by the fraction of the zone controlled by each Reference Point, which can be input as 0. Note when the DElight Daylighting Method is used, that the sum of all Reference Point control fractions must equal 1 to obtain correct overall results.

### 1.15.2.1 Inputs

#### 1.15.2.1.1 Field: Name

The name of the Daylighting:ReferencePoint object.

#### 1.15.2.1.2 Field: Zone or Space Name

The name of the [Zone](#) or [Space](#) in which the reference point is located.

#### 1.15.2.1.3 Fields: (X,Y,Z) Coordinate of Reference Point

These three fields are the X, Y and Z values of the reference point in the coordinate system you specified for daylighting reference points in the [GlobalGeometryRules](#) object. Figure 1.75 shows an example using the relative coordinate (to zone) system. Z is typically at desk height (0.8 m).

An IDF example:

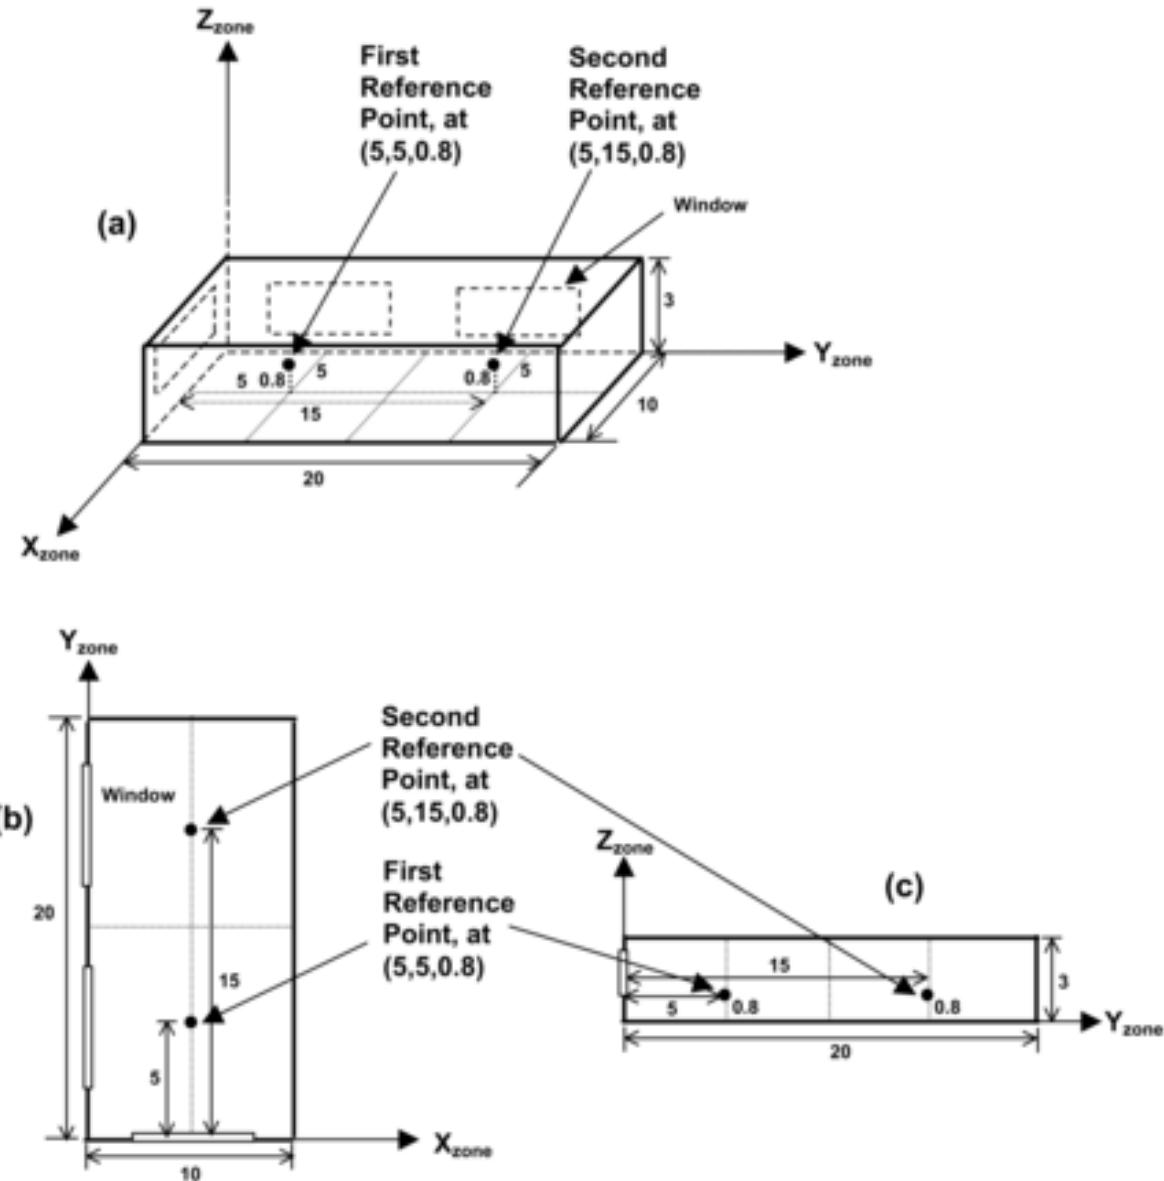

Figure 1.75: Example showing location of daylighting reference points in the zone coordinate system (relative) of a rectangular zone with three windows. (a) Perspective view, (b) plan view, (c) elevation view. All dimensions are in meters.

### 1.15.3 Guidelines for Daylighting Modeling Using the SplitFlux Method)

Following are some guidelines for preparing EnergyPlus input to model the effects of daylighting when using the SplitFlux method. Before studying these guidelines, however, you should read the description of each input field under [Daylighting:Controls](#), [Daylighting:ReferencePoint](#), and review the IDF example, above, and the sample daylighting input, PurchAirWithDaylighting.idf.

#### 1.15.3.1 Use of Window Multipliers

If an exterior wall in a daylit enclosure has a number of identical windows, the windows should be entered separately rather than using a window multiplier (ref: [FenestrationSurface:Detailed](#)). Using a multiplier would give an incorrect illuminance calculation since individual windows would not be positioned correctly on the wall.

#### 1.15.3.2 Use of Zone Multipliers

A zone multiplier should not be used on a daylit zone if the windows in the zone are shadowed by exterior obstructions like trees or neighboring buildings, or by obstructions caused by other parts of building. The reason for this is that the shadowing on the windows of the multiplied zone may be different from zone to zone depending on exactly how the shadows fall on the zones. However, a zone multiplier may be used on a daylit zone if the shadowing is by overhangs, fins and/or window setback.

#### 1.15.3.3 Thermal Zoning for Daylighting

To correctly calculate both direct and inter-reflected daylight illuminance you should try to model a thermal zone consisting of several similar rooms separated by interior walls as a representative room with a zone

multiplier (ref: Zone). An example of this is shown in Figure 1.76. Room-1 is the representative room, with a zone multiplier = 4.

Interior walls IW-1, IW-2 and IW-3 should be treated as adiabatic, i.e., they should have Outside Boundary Condition = Surface and Outside Boundary Condition Object = IW-1, IW-2, or IW-3, respectively (ref: [BuildingSurface:Detailed](#)). Similarly, if the ceiling and floor of Room-1 are interior surfaces, they should be treated as adiabatic.

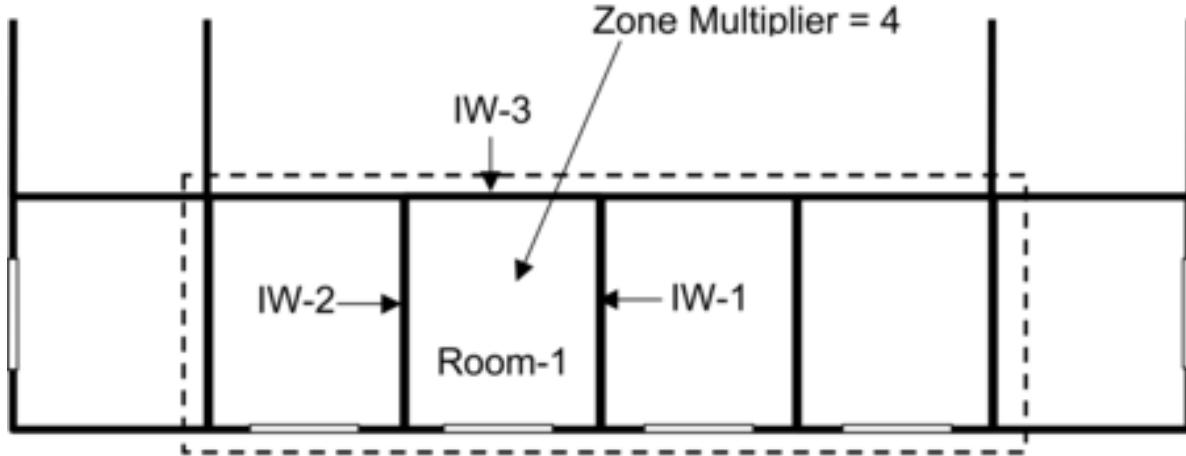

Figure 1.76: For daylighting purposes the thermal zone enclosed by the dashed boundary line should be modeled as a typical zone (Room-1) with a zone multiplier of 4.

Sometimes a representative room cannot be found. Figure 1.77 shows a section of a building with four rooms having different daylighting characteristics because of different floor area, orientation and/or window size. In this case lumping the rooms into a single thermal zone would give nonsensical daylighting illuminance values because of the presence of the interior walls, which EnergyPlus ignores when calculating illuminance reaching a reference point directly from a window (i.e., without reflection). The solution in this case is to describe each room as a separate thermal zone with its own daylighting reference points, and input the interior walls because these will participate in the calculation of inter-reflected illuminance.

#### 1.15.3.4 Multiple Lighting Zones

The daylighting control calculation allows a thermal zone or space to be divided into multiple independently-controlled lighting zones. (See the fields: Daylighting Reference Point Name, Fraction of Lights Controlled by Reference Point, and Illuminance Setpoint at Reference Point.) An example is shown in Figure 1.78, where a relatively deep thermal zone has two lighting zones of equal area.

#### 1.15.3.5 Fins, Overhangs and Other Exterior Obstructions

The daylighting calculation accounts for the presence of exterior obstructions in determining the amount of light that strikes the windows. For daylighting purposes exterior obstructions fall into three categories:

- Fins, overhangs, trees, neighboring buildings, etc., entered with the objects [Shading:Zone:Detailed](#), [Shading:Site:Detailed](#), or [Shading:Building:Detailed](#).
- Building surfaces like walls and roofs (in an L-shaped building, for example).
- Surfaces associated with window setback.

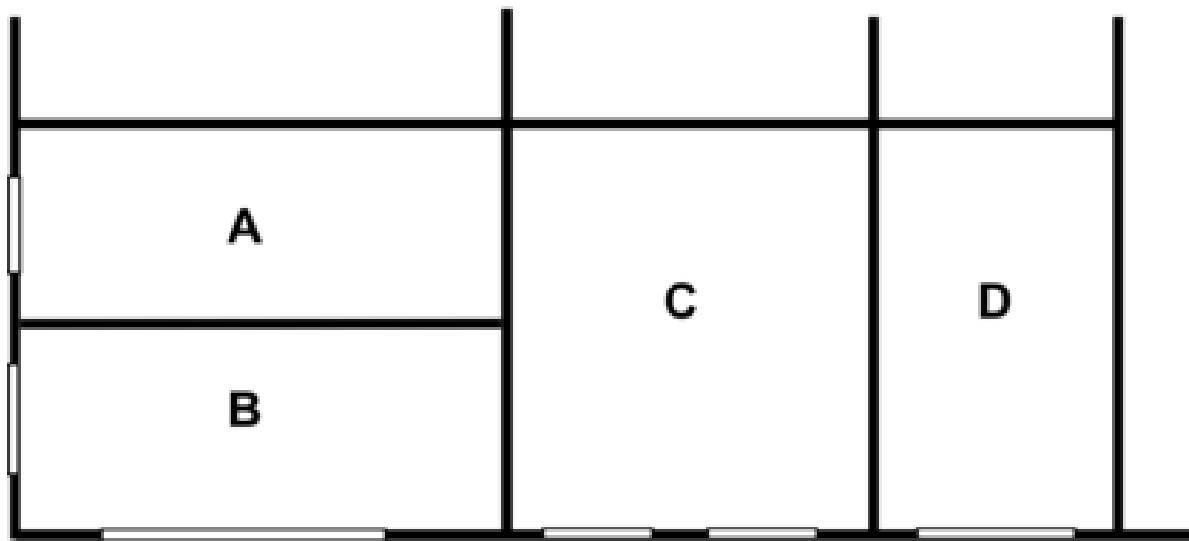

Figure 1.77: Rooms A, B, C and D have different daylighting characteristics. If lumped into a single thermal zone the daylighting calculation will be less accurate because the blockage of direct light by the interior walls between these rooms is modeled with some simplifications (see Interior Obstructions below). To get a good daylighting calculation each room should be input as a separate thermal zone.

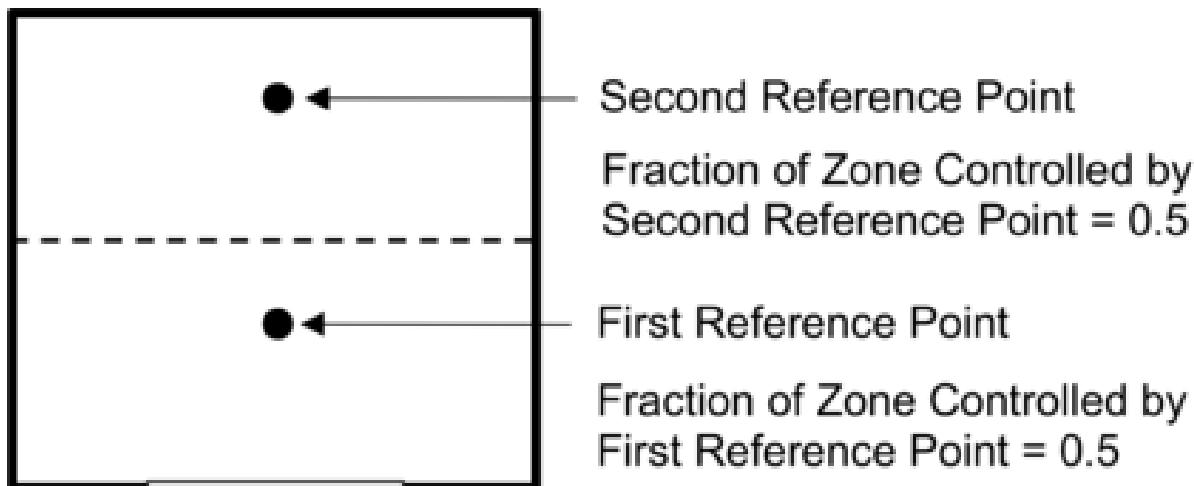

Figure 1.78: Two independently-controlled lighting zones, each with 50% of the area of the thermal zone.

Category (1) obstructions can have an associated solar transmittance schedule (see description of the field Transmittance Schedule Name for these shading surfaces). If this schedule is not specified, the surface is opaque (has zero transmittance).

The daylighting calculation takes the transmittance into account in determining, for example, how much light enters a window through a translucent awning. It is assumed that the solar and visible transmittance is the same and that the surfaces are non-diffusing, i.e., they do not change the direction of transmitted light. Ref:[Daylighting:Controls](#).

Category (2) and (3) surfaces are assumed to be opaque.

Surfaces in all three categories are assumed to be black, i.e., they do not reflect light, unless you set if “Reflections” option is chosen in the Building object. Then obstructions can reflect light, such as the top of an overhang reflecting light onto the window above. Ref: Building, Field: Solar Distribution (with reflections options).

#### 1.15.3.6 Interior Obstructions

The daylighting calculation accounts for the presence of interior obstructions that lie between a window and a reference point. Unlike exterior obstructions, which can be light transmitting, interior obstructions are assumed to be opaque. Interior obstructions can reduce or eliminate the light directly reaching the reference point through a window.

However, interior obstructions that are walls, ceilings or floors are reflecting so they contribute to the inter-reflected component of daylight illuminance as do the non-obstructing zone surfaces.

Interior obstructions can belong to the Shading object series. This type of obstruction is assumed to be non-reflecting so does not contribute to the inter-reflected component of daylight illuminance.

An example of an interior obstruction that is a wall in an L-shaped room is shown in Figure 1.79. Here, wall A (or, equivalently, Wall B) prevents light from directly getting to the Reference Point from the window.

#### 1.15.3.7 Double Façades: Daylighting through Interior Windows

The [Daylighting:Controls](#) method, with no additional user input, calculates the contribution of daylight that passes into a target zone through interior windows.[\[1\]](#) The origin of this daylight is exterior windows in adjacent zones that share interior windows with the target zone. This capability is aimed at daylighting through a **double façade** (also called “double envelope” or “double skin.”)

This is illustrated in Figure 1.80, which shows a double-façade buffer zone, Z0, with exterior windows EW1 and EW2. Z0 shares interior windows IW1, IW2 and IW3 with daylit occupied zones ZD1, ZD2 and ZD3, respectively (“daylit” here means the zone has an associated [Daylighting:Controls](#) object). The daylight illuminance at reference points RP1, RP2 and RP3 comes from the interior windows and has two main sources:

- Daylight that passes through both an exterior window and an interior window in Z0 and reaches a reference point without reflection. This is called “direct illuminance.”
- Daylight from Z0 that passes through an interior window and reaches a reference point by inter-reflection in the daylit zone. Because the program calculates this source from the interior solar distribution in Z0 it is recommended that the most accurate calculation of this distribution be made, which occurs if Solar Distribution = FullInteriorAndExterior in the Building object.

A third possible source is neglected because it is generally small in double-façade cases. This is daylight that is reflected from the surfaces of Z0, passes through an interior window and then reaches a reference point without inter-reflection in the daylit zone.

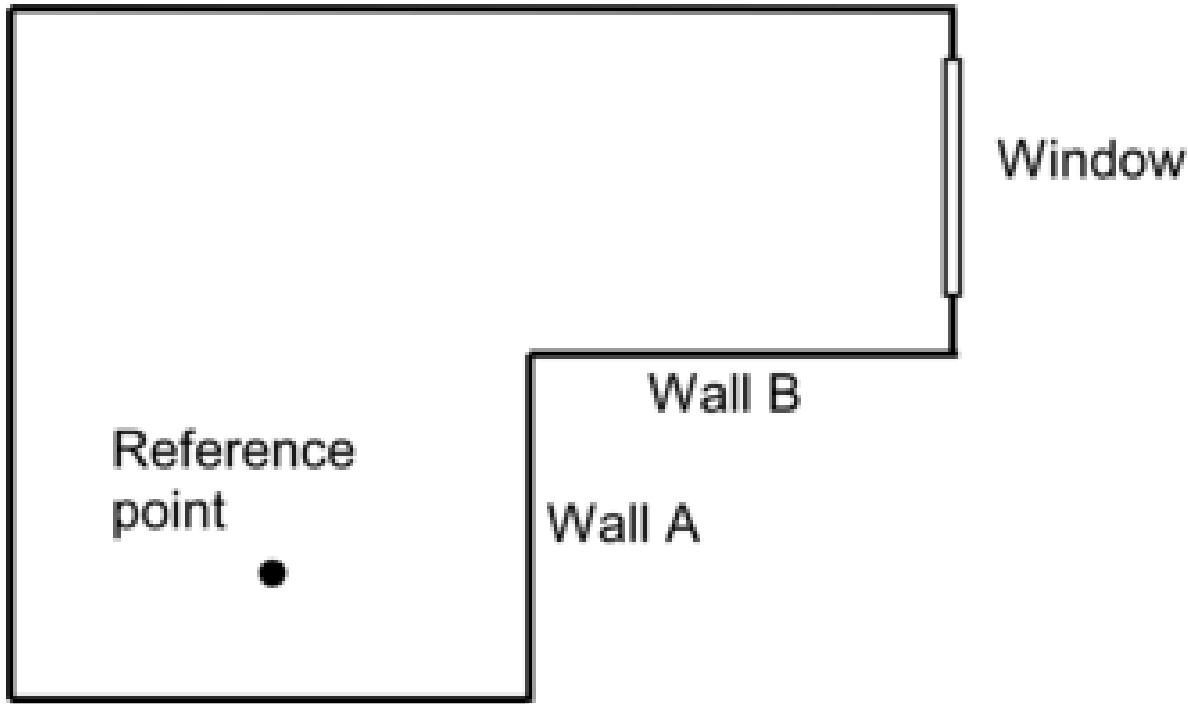

Figure 1.79: Wall A (or Wall B) is an interior obstruction that prevents light from directly reaching the daylighting reference point from the window.

PurchAirWithDoubleFacadeDaylighting.idf is an input example of daylighting through an interior window.

### 1.15.3.8 Interior Window Daylighting Configurations that EnergyPlus Can Calculate

Figure 1.81 shows schematically the general configuration of daylighting through interior windows that can be calculated with EnergyPlus. Here, daylit zone ZD has one or more interior windows that are adjacent to other zones, each of which has one or more exterior windows. ZD itself may or may not have exterior windows. If it does, than the daylight illuminance from its exterior and interior windows will be additive. The zones adjacent to ZD may or may not be daylit and may or may not have other interior windows that are not adjacent to ZD. (The program does not consider the illuminance in ZD from electric lighting in adjacent zones.)

### 1.15.3.9 Interior Window Daylighting Configurations that EnergyPlus Cannot Calculate

Figure 1.82 shows schematically a configuration of daylighting through interior windows that cannot be calculated with EnergyPlus. Here, zone Z has an interior window that is adjacent to zone Z1 which in turn has an interior window adjacent to zone Z2. However, the daylight from the exterior window in Z2 that enters Z after passing through Z1 is not calculated because Z2 is not adjacent to Z.

### 1.15.3.10 Restrictions on Shading Devices

There are two restrictions on the use of exterior-window shading devices when a daylit zone has interior windows:

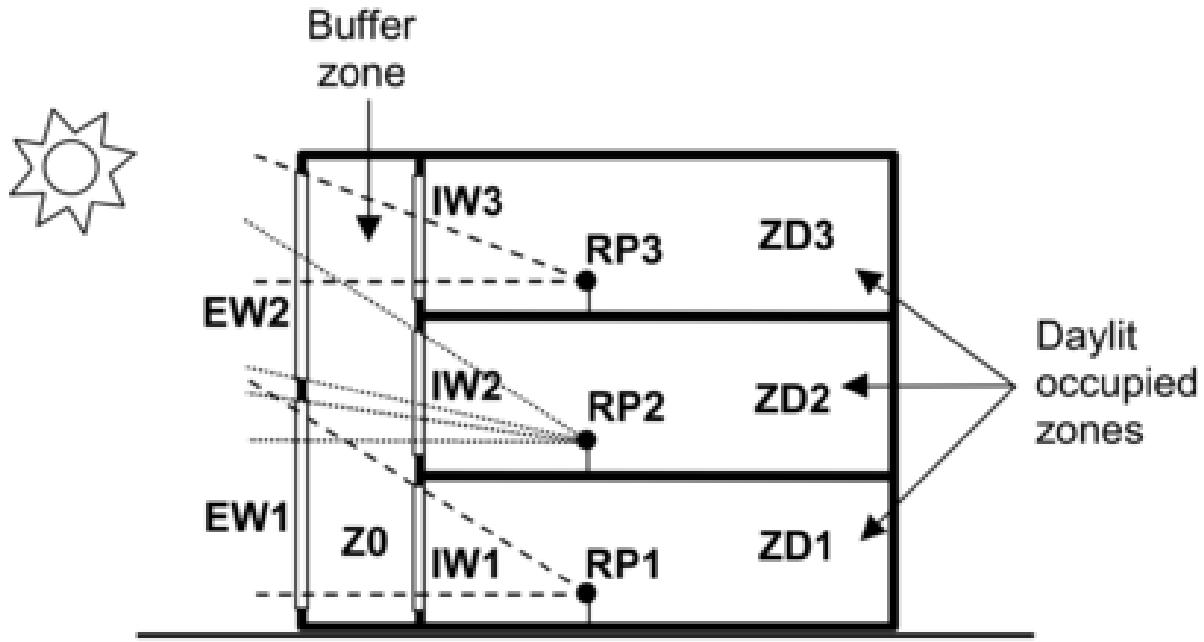

Figure 1.80: Vertical section through a double-façade building showing daylighting through interior windows. The dashed lines show that (1) reference point RP1 receives direct light from exterior window EW1 via interior window IW1; (2) RP2 receives direct light from EW1 and EW2 via IW2; and (3) RP3 receives direct light from EW2 via IW3.

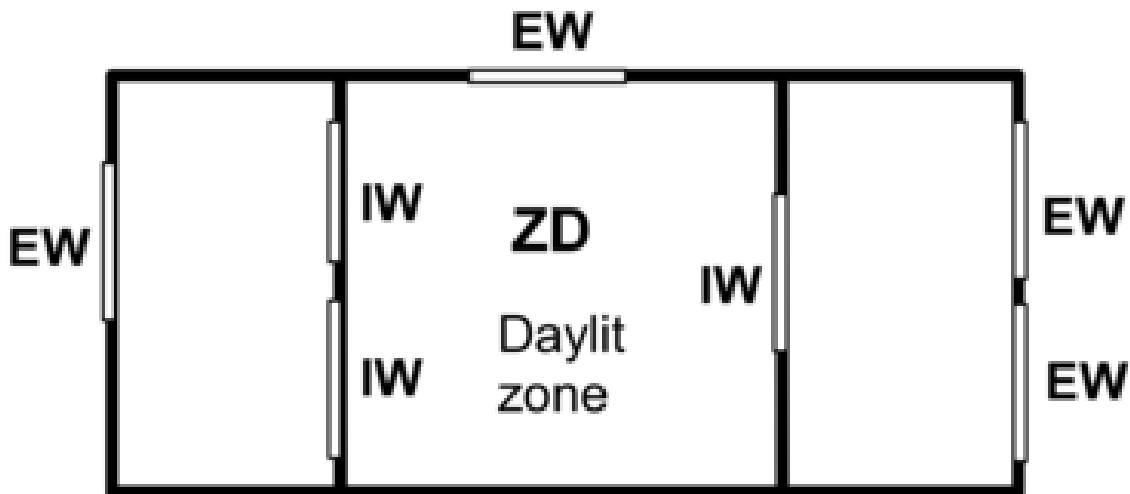

Figure 1.81: General configuration of daylighting through interior windows that can be calculated with EnergyPlus. IW = interior window, EW = exterior window.

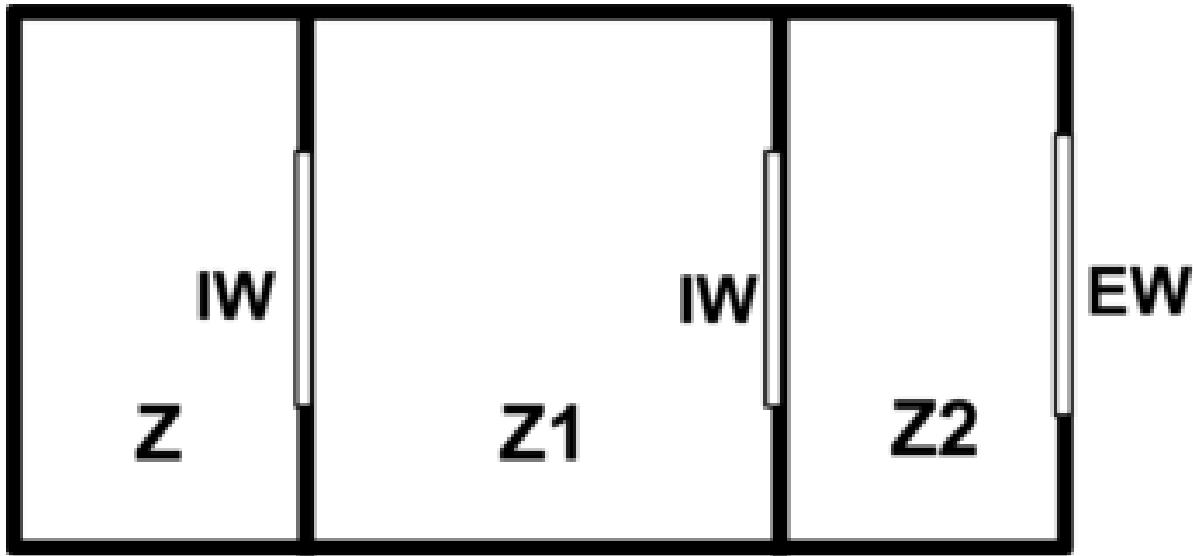

Figure 1.82: Configuration in which daylighting of zone Z through its interior window cannot be calculated with EnergyPlus. IW = interior window, EW = exterior window.

- 1) If two daylit zones share an interior window, neither zone can have an exterior window whose shading device does glare control (i.e., the **WindowShadingControl** for the exterior window has **Glare Control Is Active** = Yes).
- 2) If two daylit zones share an interior window, neither zone can have an exterior window with a **WindowShadingControl** that has **Shading Control Type** = **MeetDaylightIlluminanceSetpoint**.

#### 1.15.4 DElight Daylighting Method

The DElight method of analyzing daylighting in buildings is very similar to that used in the SplitFlux method and uses the same **Daylighting:Controls** and **Daylighting:ReferencePoint** objects but the Daylighting Method should be set to DElight. For each point in time, DElight calculates the interior daylighting illuminance at specified reference points and then determines how much the electric lighting can be reduced while still achieving a combined daylighting and electric lighting illuminance target. The daylight illuminance level in a zone depends on many factors, including exterior light sources; location, size, and visible light transmittance of simple and complex fenestration systems; reflectance of interior surfaces; and location of calculation reference points. The subsequent reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled, and type of lighting control.

There are two primary differences between the SplitFlux and DElight methods of calculating interior illuminance levels. The first is that DElight includes the capability of analyzing complex fenestration systems that include geometrically complicated shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). The second key difference is that DElight uses a radiosity method to calculate the effects of light reflection inside a zone. These methods are discussed in more detail in the engineering documentation.

There are other important differences between the two methods. One is the inability of DElight to perform the type of dynamic shading controls possible using the SplitFlux method at each point in time during the thermal simulation (e.g., changes in electrochromic glazing transmittances and blind slat angles). A second is the current lack of visual quality (e.g., glare) calculations performed by DElight.

Third, the modeling of interior obstructions is different in the two methods. In the DElight method interior obstructions block interreflections but do not block the initial direct illuminance. In the SplitFlux method, interior obstructions block the initial direct illuminance but do not block interreflections. See the engineering documentation for more details. Fourth, when using DElight daylighting the presence of exterior shading surfaces such as overhangs is ignored.

Input for invoking the DElight method involves three object types: [Daylighting:Controls](#), [Daylighting:ReferencePoint](#), and [Daylighting:DELight:ComplexFenestration](#).

### 1.15.5 Daylighting:DELight:ComplexFenestration

Another input object that can only be used when the DElight Daylighting Method is used is the Daylighting:DElight:ComplexFenestration object. The DElight daylighting analysis method can be applied to daylighting zones that contain only simple fenestration systems such as windows and skylights that are standard EnergyPlus sub-surfaces. In this situation, no Daylighting:DElight:ComplexFenestration object would be input.

In addition to analyzing simple fenestration systems, DElight includes the capability of analyzing complex fenestration systems such as geometrically complicated static shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). This capability is based on characterizing these complex fenestration systems (CFS) using bi-directional transmittance distribution functions (BTDF). In general, BTDF data for a specific CFS must be either measured or simulated (e.g., using ray-tracing techniques) prior to employing DElight to analyze it within EnergyPlus. The current implementation of DElight CFS calculations within EnergyPlus supports two approaches to the input of BTDF, an analytical approach and a file-based approach. The details of inputting these two approaches are described below under the User Complex Fenestration Type field.

Two analytical CFS BTDF types are currently supported, window and light shelf. The file-based approach requires that a user has access to a data file containing raw BTDF data that DElight reads as additional input during its analysis calculations. BTDF data files are described separately since it is anticipated that individual EnergyPlus users will not create these data files themselves.

The methods related to characterizing and analyzing CFS using BTDF are still evolving. DElight is an early implementation of CFS analysis methods. These methods, and the input associated with them here, will likely change in the future.

#### 1.15.5.1 Inputs

##### 1.15.5.1.1 Field: User Name

User name of the DElight daylighting Complex Fenestration to which the following input applies.

##### 1.15.5.1.2 Field: Complex Fenestration Type

Type name of the DElight daylighting Complex Fenestration system to be analyzed. This type name must take one of the following two forms.

```
BTDF^GEN^Analytical Type^Normal Visible Transmittance^Dispersion Angle
BTDF^FILE^Filename
```

The first form above is for supported analytical CFS types which currently include WINDOW and LIGHTSHELF. While these analytical types are relatively simple, they represent flexible ways to explore diffusing CFS systems and the impact of light shelves in redirecting light through an aperture. Each of these types also requires the visible transmittance of the CFS at normal incidence angle, and a dispersion angle (in degrees) that represents the “spread” of transmitted light. A small dispersion angle of 10 corresponds

to clear glazing while a large angle of 90 corresponds to perfectly diffusing glazing. The “ $\wedge$ ” symbol must be used as a delimiter between sub-fields within this Complex Fenestration type name string as shown in the IDF example for WINDOW below, and in the DElight sample input data files.

The second form above is for CFS types for which there is pre-measured or pre-simulated BTDF data. In this case the Filename sub-field must be a valid data file name that is associated with an existing BTDF dataset that DElight can use in its calculations.

#### 1.15.5.1.3 Field: Building Surface Name

The name of the heat transfer surface object instance hosting this Complex Fenestration, analogous to the Building Surface Name field for subsurfaces such as Windows. This must be a valid name that has been associated with a heat transfer surface contained in the same EnergyPlus input data file.

#### 1.15.5.1.4 Field: Window Name

The name of the Window (ref: [FenestrationSurface:Detailed](#) object) instance that will be used to account for the geometry, and the solar/thermal gains/losses, of the Complex Fenestration system surface. This must be a valid name that has been associated with a Window contained in the same EnergyPlus input data file. The geometry for the Complex Fenestration is taken from the geometry input for this standard EnergyPlus subsurface, hence the term “Doppelganger.”

Note that DElight only deals with the visible spectrum of light transmitted through a Complex Fenestration. To account for the solar/thermal influences of a Complex Fenestration, a geometrically coincident subsurface that will be accounted for by methods already within EnergyPlus must be defined in the input data file. This is an interim solution to the issue of accounting for solar/thermal influences that will likely change as techniques analogous to the daylighting analysis of BTDF are developed.

#### 1.15.5.1.5 Field: Fenestration Rotation

The in-plane counter-clockwise rotation angle between the Complex Fenestration optical reference direction and the base edge of the Doppelganger Surface geometry. The Complex Fenestration optical reference direction is the direction of the zero azimuth angle for the BTDF dataset. This Rotation angle will typically be zero when the Doppelganger surface is rectangular and its width edge is aligned with the Complex Fenestration optical reference direction.

An IDF example for an analytical WINDOW type CFS:

```
Daylighting:DELight:ComplexFenestration,
    Window CFS,          !- DELight Complex Fenestration User Name
    BTDF^GEN^WINDOW^1.0^20.0,      !- Complex Fenestration Type
    ZN003:WALL001,   !- Complex Fenestration Host Surface
    Zn003:Wall001:Doppel001, !- Doppelganger Surface Name
    0.0;                !- Fenestration Rotation {deg}
```

#### 1.15.5.2 Outputs

The following daylighting-specific outputs are available for Daylighting:Controls:

- Zone,Average,Site Exterior Beam Normal Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Beam Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Sky Illuminance [lux]
- Zone,Average,Site Beam Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]

- Zone,Average,Site Daylighting Model Sky Clearness []
- Zone,Average,Site Daylighting Model Sky Brightness []
- Surface,Average,Daylighting Window Reference Point <x> View Luminance [cd/m<sup>2</sup>]
- Surface,Average,Daylighting Window Reference Point <x> Illuminance [lux]
- Zone,Average,Daylighting Reference Point <x> Illuminance [lux]
- Zone,Average,Daylighting Reference Point <x> Glare Index []
- Zone,Sum,Daylighting Reference Point <x> Glare Index Setpoint Exceeded Time [hr]
- Zone,Sum,Daylighting Reference Point <x> Daylight Illuminance Setpoint Exceeded Time [hr]
- Zone,Average,Daylighting Lighting Power Multiplier []

#### **1.15.5.2.1 Site Exterior Beam Normal Illuminance [lux]**

Beam normal illuminance of the sun at the earth's surface, measured in lux (lumens/m<sup>2</sup>)

#### **1.15.5.2.2 Site Exterior Horizontal Beam Illuminance [lux]**

Beam illuminance on an unobstructed horizontal plane at the earth's surface. Equals "Site Exterior Beam Normal Illuminance" times sine of solar altitude.

#### **1.15.5.2.3 Site Exterior Horizontal Sky Illuminance [lux]**

Illuminance from sky solar radiation on an unobstructed horizontal plane at the earth's surface. The total exterior horizontal illuminance is the sum of "Site Exterior Horizontal Beam Illuminance" and "Site Exterior Horizontal Sky Illuminance."

#### **1.15.5.2.4 Site Beam Solar Radiation Luminous Efficacy [lum/W]**

A measure of the visible light content of beam solar radiation; equal to the number of lumens per watt of beam solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

#### **1.15.5.2.5 Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]**

A measure of the visible light content of sky diffuse solar radiation; equal to the number of lumens per watt of sky diffuse solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

#### **1.15.5.2.6 Site Daylighting Model Sky Clearness []**

Clearness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*). Sky Clearness close to 1.0 corresponds to an overcast sky. Sky Clearness > 6 is a clear sky.

#### **1.15.5.2.7 Site Daylighting Model Sky Brightness []**

Brightness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*).

**1.15.5.2.8 Daylighting Window Reference Point <x> View Luminance [cd/m<sup>2</sup>]**

The area-averaged luminance of an exterior window as viewed from the first reference point in the daylit zone containing the window. In general, higher window luminance values are associated with higher daylight glare values. (Printed only for exterior windows in daylit zones without interior windows.)

**1.15.5.2.9 Daylighting Window Reference Point <x> Illuminance [lux]**

The contribution from a particular exterior window to the daylight illuminance at the first reference point in the daylit zone containing the window. (Not printed for exterior windows in daylit zones with interior windows.)

**1.15.5.2.10 Daylighting Reference Point <x> Illuminance [lux]**

The total daylight illuminance at the first reference point from all of the windows in a daylit zone.

**1.15.5.2.11 Daylighting Reference Point <x> Glare Index []**

The daylight glare index at the first reference point in a daylit zone.

**1.15.5.2.12 Daylighting Reference Point <x> Glare Index Setpoint Exceeded Time [hr]**

The number of hours when the calculated daylight glare index at the first reference point exceeds the glare index setpoint.

**1.15.5.2.13 Daylighting Reference Point <x> Daylight Illuminance Setpoint Exceeded Time [hr]**

The number of hours when the calculated daylight illuminance at the first reference point exceeds the daylight illuminance setpoint.

**1.15.5.2.14 Daylighting Lighting Power Multiplier []**

The amount by which the overhead electric lighting power in a space or zone is multiplied due to usage of daylighting to dim or switch electric lights. For example, if the multiplier is M and the electric power without dimming is P, then the electric power with dimming is M\*P. The multiplier varies from 0.0, which corresponds to maximum dimming (zero electric lighting), to 1.0, which corresponds to no dimming.

**1.15.6 Output:IlluminanceMap**

The Output:IlluminanceMap object expands on the reporting capabilities of the daylighting simulation. For any zone simulated with [Daylighting:Controls](#), the illuminance map can generate up to 2,500 points of additional daylighting illuminance values. The resulting map is output as a comma delimited text file that can be imported into a spreadsheet program for rapid visualization of the daylighting illuminance patterns in a zone. The values are produced on an hourly basis. The Z height of the map is constant (parallel to a flat floor). More than one illuminance map can be created for a zone. IlluminanceMap output is available only when SplitFlux daylighting method is selected in [Daylighting:Controls](#) object.

**1.15.6.1 Inputs****1.15.6.1.1 Field: Name**

The name of the map object.

### 1.15.6.1.2 Field: Zone Name

Reference to a zone with Daylighting:Controls. The zone must lie completely within a single solar enclosure.

### 1.15.6.1.3 Field: Z Height

The height or elevation of the grid of daylighting points.

### 1.15.6.1.4 Field: X Minimum Coordinate

The minimum X coordinate boundary for the map.

### 1.15.6.1.5 Field: X Maximum Coordinate

The maximum X coordinate boundary for the map.

### 1.15.6.1.6 Field: Number of X Grid Points

The number of daylighting reference points in the X direction from the minimum to the maximum boundaries. The maximum number of points that can be generated is 2500 (Number of X Grid Points X Number of Y Grid Points).

### 1.15.6.1.7 Field: Y Minimum Coordinate

The minimum Y coordinate boundary for the map.

### 1.15.6.1.8 Field: Y Maximum Coordinate

The maximum Y coordinate boundary for the map.

### 1.15.6.1.9 Field: Number of Y Grid Points

The number of daylighting reference points in the Y direction from the minimum to the maximum boundaries. The maximum number of points that can be generated is 2500 (Number of X Grid Points X Number of Y Grid Points).

Note: Daylighting factors cannot be accurately calculated for reference points that are very close to a wall or window (less than 0.15 m or 6 inches). An error is reported for a reference point that is too close to a window, but no error is reported for a point that is too close to a wall.

```
Output:IlluminanceMap,
  Daylit Map,      ! Map Name
  Daylit Zone,    ! Zone Name
  0,              ! Z Height [m]
  0.1,            ! X Minimum Coordinate [m]
  4.9,            ! X Maximum Coordinate [m]
  10,             ! Number of X Grid Points
  0.1,            ! Y Minimum Coordinate [m]
  9.9,            ! Y Maximum Coordinate [m]
  10;             ! Number of Y grid Points
```

Since not all zones are rectangular, it is possible to have map points that are outside the zone. Any illuminance registered at these points is inaccurate and, additionally, a “\*” marks these values for easy observance.

## 1.15.7 OutputControl:IlluminanceMap:Style

This object specifies the “style” for the illuminance map output (described in the Output Details and Examples document). As described early in the document (see: EnergyPlus Output Processing), the user may select the “style” for the daylighting illuminance map output file (eplusmap.<ext>).

### 1.15.7.1 Inputs

#### 1.15.7.1.1 Field: Column Separator

For this field, the desired separator for columns is entered. “Comma” creates comma separated fields/columns in the outputs (eplusmap.csv file is created). “Tab” creates tab separated fields/columns in the outputs (eplusmap.tab file is created). “Fixed” creates space separated fields/columns in the outputs (eplusmap.txt file is created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel<sup>TM</sup> or other spreadsheet programs. The tab delimited files can also be viewed by text editors, word processing programs and easily converted to “tables” within those programs.

## 1.15.8 Daylighting Devices

Daylighting devices work in conjunction with the **Daylighting:Controls** object to simulate components that can improve daylighting in a zone.

Daylighting devices are also tightly integrated into the zone heat balance. The thermal effects of these devices are simulated with or without the use of a **Daylighting:Controls** object.

There are two types of daylighting device in EnergyPlus: tubular daylighting devices and daylight shelves.

## 1.15.9 DaylightingDevice:Tubular

Tubular daylighting devices (TDDs), also known as tubular skylights or light pipes, are used to bring natural exterior daylight into the hard-to-reach, interior spaces of a building.

TDDs consist of three components: a dome, a pipe, and a diffuser.

In EnergyPlus each of these components corresponds to an object in the input file.

The dome and diffuser are defined in the same way as windows using the **FenestrationSurface:Detailed** object. The *Surface Type* field must be specified as **TubularDaylightDome** or **TubularDaylightDiffuser** accordingly.

The location and orientation of the dome surface affect the total amount of daylight collected.

The *Base Surface* of the diffuser object determines to which zone the daylighting is delivered. The location and orientation of the diffuser surface affect the amount of daylight received at the **Daylighting:Controls** reference points.

Although the object definition is the same as for a window, there are several restrictions on **TubularDaylightDome** and **TubularDaylightDiffuser** objects:

- Shading control devices are not allowed.
- Frames and dividers are not allowed.
- Multipliers must be 1.0.
- Dome, diffuser, and pipe areas (as given by diameter) must be approximately equal.
- Outside face environment objects are not allowed.
- Dome and diffuser constructions cannot be more than one layer.

Since commercial TDDs are assumed to be cylindrical in shape, it is recommended that the circular areas of the actual dome and diffuser be approximated with a square of equivalent area for the **TubularDaylightDome** and **TubularDaylightDiffuser** objects. Although it is possible to use a triangular surface instead, a square is a much better geometric approximation of a circle.

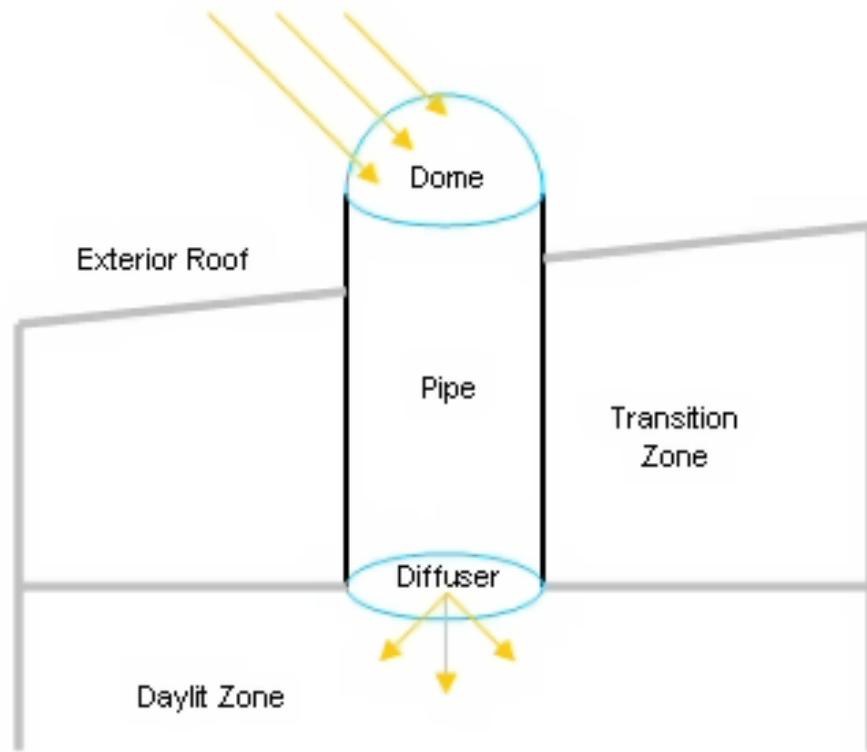

Figure 1.83: Tubular daylighting device diagram.

Note that the `TubularDaylightDome` surface is allowed to have a different position and tilt from the roof base surface. If the actual TDD projects some height above the roof surface, the `TubularDaylightDome` coordinates should be located accordingly.

The `TubularDaylightDome` surface automatically casts a shadow on the roof base surface. However, since the pipe is not represented by a surface, it will not cast a shadow. If this effect must be simulated, one or more `SURFACE:SHADING` objects can be used.

The dome and diffuser objects are connected by the `DAYLIGHTING DEVICE:TUBULAR` object:

### 1.15.9.1 Inputs

#### 1.15.9.1.1 Field: Name

The name of the TDD object.

#### 1.15.9.1.2 Field: Dome Name

Reference to a `FenestrationSurface:Detailed` object with *Surface Type* `TubularDaylightDome`.

#### 1.15.9.1.3 Field: Diffuser Name

Reference to a `FenestrationSurface:Detailed` object with *Surface Type* `TubularDaylightDiffuser`.

#### 1.15.9.1.4 Field: Construction Name

The construction of the TDD pipe. The visible and solar absorptance of the inside material layer determines the reflectivity of the inner mirrored surface of the TDD. This is very important for the overall transmittance of the TDD.

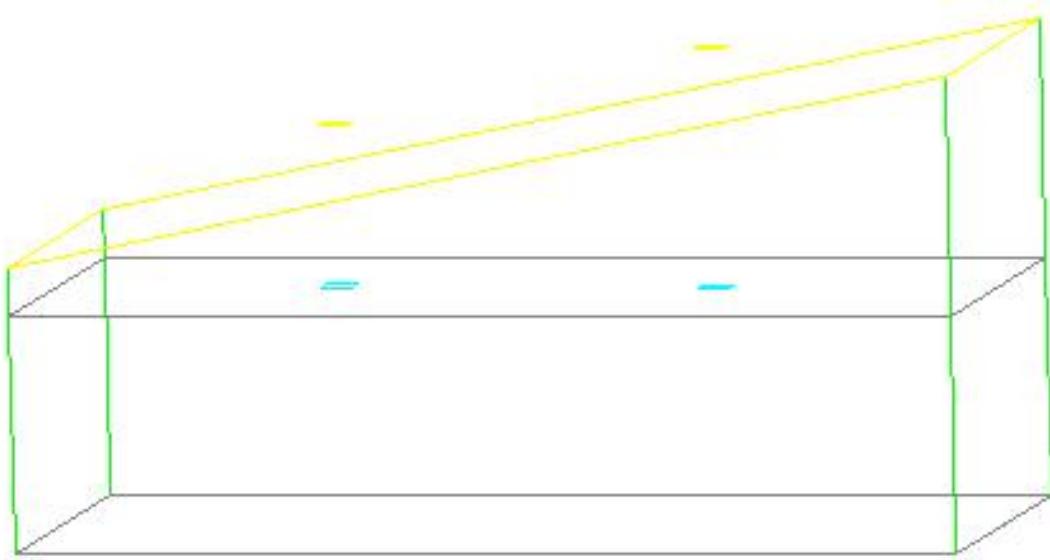

Figure 1.84: Tubular daylighting device DXF output.

#### 1.15.9.1.5 Field: Diameter

The diameter [m] of the TDD pipe. The area of the pipe must match the areas of the dome and diffuser.

#### 1.15.9.1.6 Field: Total Length

The total length [m] of the TDD pipe between the dome and the diffuser, including the exterior part above the roof. The exterior length is determined internally by subtracting the transition zone lengths from the total length.

#### 1.15.9.1.7 Field: Effective Thermal Resistance

The effective thermal resistance [ $m^2 \cdot K/W$ ], i.e. R-value, of the TDD between the exterior dome surface and the interior diffuser surface.

#### 1.15.9.1.8 Field: Transition Zone<#> Name

Name of zone that the TDD pipe passes through before reaching the delivery zone.

#### 1.15.9.1.9 Field: Transition Zone <#> Length

Length of pipe [m] in the transition zone. This is used for determining heat gains due to solar absorbed by the pipe in each transition zone. The distribution of absorbed solar gains can be customized by adjusting the length of pipe in each transition zone. The transition zone gain is proportional to the length of pipe in the zone. If no transition zones are specified, all solar absorbed by the pipe is lost to the exterior environment.

The *Transition Zone Name* and *Transition Zone Length* fields can be repeated for additional transition zones.

```

### 1.15.9.2 Outputs

- Zone,Average,Tubular Daylighting Device Transmitted Solar Radiation Rate [W]
- Zone,Average,Tubular Daylighting Device Pipe Absorbed Solar Radiation Rate [W]
- Zone,Average,Tubular Daylighting Device Heat Gain Rate [W]
- Zone,Average,Tubular Daylighting Device Heat Loss Rate [W]
- Zone,Average,Tubular Daylighting Device Beam Solar Transmittance []
- Zone,Average,Tubular Daylighting Device Beam Visible Transmittance []
- Zone,Average,Tubular Daylighting Device Diffuse Solar Transmittance []
- Zone,Average,Tubular Daylighting Device Diffuse Visible Transmittance []

#### 1.15.9.2.1 Tubular Daylighting Device Beam Solar Transmittance []

This is the transmittance of beam solar radiation through the TDD.

#### 1.15.9.2.2 Tubular Daylighting Device Beam Visible Transmittance []

This is the transmittance of beam visible radiation, or daylight, through the TDD.

**1.15.9.2.3 Tubular Daylighting Device Diffuse Solar Transmittance []**

This is the transmittance of diffuse solar radiation through the TDD.

**1.15.9.2.4 Tubular Daylighting Device Diffuse Visible Transmittance []**

This is the transmittance of diffuse visible radiation, or daylight, through the TDD.

**1.15.9.2.5 Tubular Daylighting Device Heat Gain Rate [W]**

This is the rate of heat gain to the zone by the TDD, in Watts.

**1.15.9.2.6 Tubular Daylighting Device Heat Loss Rate [W]**

This is the rate of heat loss from the zone by the TDD, in Watts.

**1.15.9.2.7 Tubular Daylighting Device Pipe Absorbed Solar Radiation Rate [W]**

This is the rate at which solar radiation is absorbed by the pipe in the TDD, in Watts.

**1.15.9.2.8 Tubular Daylighting Device Transmitted Solar Radiation Rate [W]**

This is the rate at which solar radiation is transmitted by the TDD, in Watts.

In addition, several surface and window variables are also reported for the TubularDaylightDome and TubularDaylightDiffuser objects. For the TubularDaylightDome:

- Zone,Average,Surface Outside Face Sunlit Area [m<sup>2</sup>]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

For the TubularDaylightDiffuser:

- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m<sup>2</sup>] (*incident inside of pipe*)
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W] (*same as Tubular Daylighting Device Transmitted Solar Radiation Rate*)
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

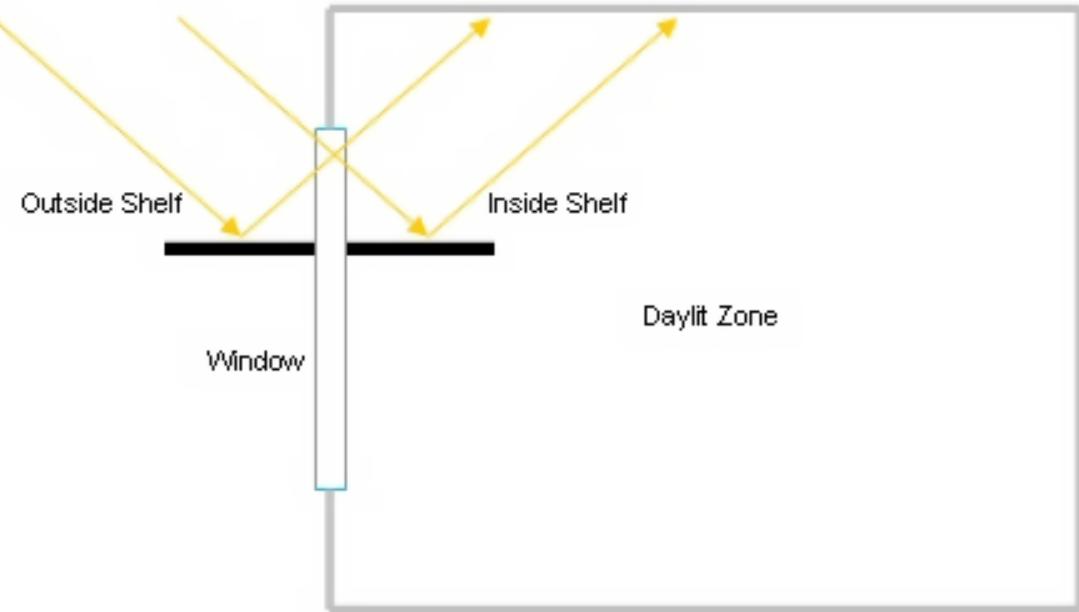

Figure 1.85: Daylighting shelf diagram.

### 1.15.10 DaylightingDevice:Shelf

Daylighting shelves, or simply light shelves, are another device for bringing more daylight into a building. Installed as an accessory to a window, daylighting shelves work by reflecting exterior light onto the ceiling of a room. Daylighting shelves can have an inside shelf, an outside shelf, or both.

The inside shelf redistributes light that would have entered the zone anyway. Instead of entering as a beam, all light is reflected onto the zone ceiling and is converted to diffuse shortwave radiation.

The outside shelf changes the amount of light entering the zone. If the shelf surface is more reflective than the ground, it can increase the amount of light incident on the upper part of the window. However, the shading effect of the outside shelf on the lower part of the window must also be considered as it can easily negate any gain achieved in the upper part of the window. All light reflected from the outside shelf that enters the upper window is assumed to strike the ceiling.

In EnergyPlus a daylighting shelf is simulated using a DaylightingDevice:Shelf object in combination with up to three other objects: a window, a heat transfer surface, and an attached shading surface.

The window must be divided into two window surfaces: an upper window and a lower window. The upper window interacts directly with the daylighting shelf object and is not allowed to have any shading control devices or frames or dividers. The lower window does not interact with the daylighting shelf object, but does receive shading from the outside shelf. There are no restrictions on the lower window.

The inside shelf is defined as a regular heat transfer surface in the zone. However, the surface must have the *Outside Boundary Condition* field set to Surface with itself as the other zone surface. Shading and thermal mass effects are taken into account.

The outside shelf is defined as a **Shading:Zone:Detailed** object. The visible and solar absorptance of the outside material layer determines the reflectivity of the shelf.

**NOTE:** Unlike a regular **Shading:Zone:Detailed** object, the vertices of the outside shelf surface must be ordered so that the outward normal vector points *upward*, i.e. toward the upper window. This is necessary in order for the outside shelf to properly receive sunlight and shading from other

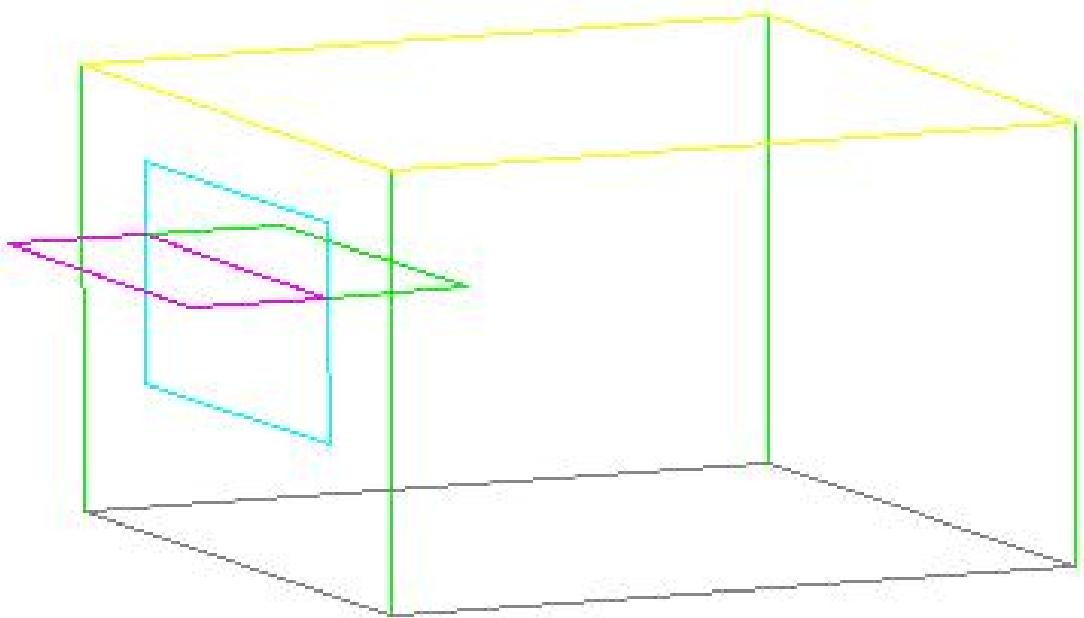

Figure 1.86: Daylighting shelf DXF output.

surfaces. A mirror shading surface with the outward normal vector pointing in the opposite direction is automatically created by the program to shade the lower window.

The inside shelf and outside shelf are both optional. However, if neither shelf is specified, the daylighting shelf object has no effect on the simulation.

### 1.15.10.1 Inputs

#### 1.15.10.1.1 Field: Name

The name of the daylighting shelf object.

#### 1.15.10.1.2 Field: Window Name

Reference to a **FenestrationSurface:Detailed** object with *Surface Type* WINDOW.

#### 1.15.10.1.3 Field: Inside Shelf Name

Reference to a **BuildingSurface:Detailed** object. This field is optional. If used, this surface must have OTHERZONESURFACE specified for the *Outside Face Environment* field and the referenced other zone surface must be itself. The number of vertices of this surface object must be 4.

#### 1.15.10.1.4 Field: Outside Shelf Name

Reference to a **ShadingZone:Detailed** object. This field is optional. If used, the number of vertices of this surface object must be 4.

### 1.15.10.1.5 Field: Outside Shelf Construction Name

Reference to a CONSTRUCTION object. This field is required if an outside shelf is specified. The visible and solar absorptance of the outside material layer determines the shelf reflectivity.

### 1.15.10.1.6 Field: View Factor To Outside Shelf

User defined value for the view factor from the window to the outside shelf. This field is optional. If not specified, an exact view factor is calculated for two perpendicular rectangles of the same width having a shared edge. If the given surfaces do not meet these geometric requirements, it is necessary to specify a value here.

**NOTE:** It is up to the user to adjust the view factor to ground of the upper window to account for the part of the view blocked by the outside shelf. The calculated *View Factor To Outside Shelf* is reported in the eio file for this purpose. For the typical case where the shelf is parallel to the ground and the upper window is perpendicular to the ground, the view factor to ground is simply:  $0.5 - \text{View Factor To Outside Shelf}$ .

```

### 1.15.10.2 Outputs

The view factor to outside shelf calculation shows up in the .eio file along with the associated window and window view factors to sky and ground:

! <Shelf Details>,Name,View Factor to Outside Shelf,Window Name,Window View Factor to Sky,Window View Factor to Ground

SHELF,0.29,DAYLIT UPPER WINDOW,0.50,0.21

This variable reports the calculated *View Factor To Outside Shelf* so that the user can correctly adjust the view factor to ground of the upper window.

The usual window and surface variables are relevant for the upper window:

- Zone,Average,Surface Outside Face Sunlit Area [m<sup>2</sup>]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]
- Zone,Average,Surface Window Heat Gain Rate [W]
- Zone,Average,Surface Window Heat Loss Rate [W]

The following surface variables are reported for the outside shelf surface, if specified:

- Zone,Average,Surface Outside Face Sunlit Area [m<sup>2</sup>]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m<sup>2</sup>]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]

### 1.15.11 DaylightingDevice:LightWell

This object is used to model the impacts on daylighting of a “light well” that might be associated with exterior windows such as skylights. The light well model attenuates the light transmitted by the skylight. The attenuation is characterized by the **well efficiency**, which is the ratio of the amount of light leaving the well to the amount of light entering the well. The well efficiency varies from close to 1.0 to close to zero if there is high attenuation. The well efficiency is used only in the EnergyPlus detailed daylighting calculation, where it multiplies the beam and diffuse light transmitted by the skylight. (The well efficiency is not used in calculating the solar gain through the skylight.)

The input object describes the light well using basic characteristics of the geometry along with the visible reflectance of the well’s side walls. The following figure diagrams how the geometry is characterized.

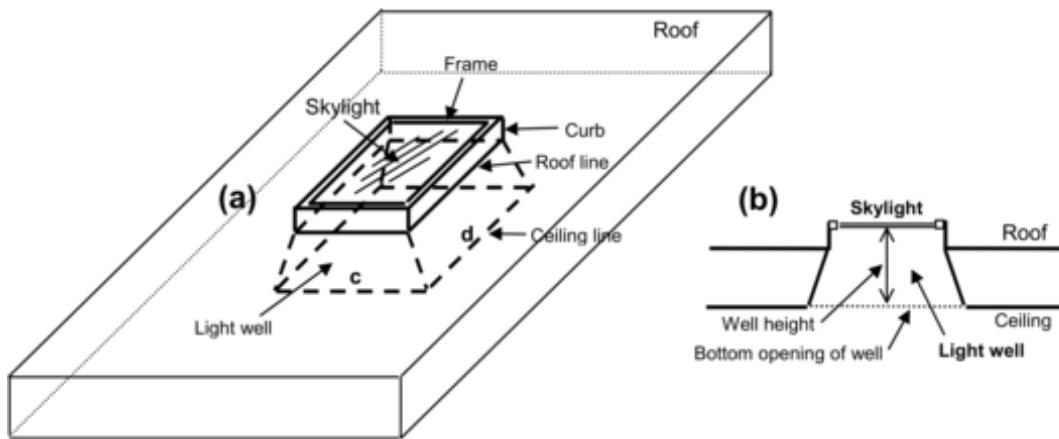

Figure 1.87: Skylight with light well: (a) perspective view, (b) vertical section. If the bottom of the light well is a rectangle of side lengths  $c$  and  $d$ , as shown in (a), then the perimeter of the bottom of the well =  $2(c+d)$  and the area =  $cd$  (see description of field names for the Light Well object).

#### 1.15.11.1 Inputs

##### 1.15.11.1.1 Field: Exterior Window Name

The name of the exterior window that this Light Well is associated with. Generally this is a skylight in a roof. However, light wells can be applied to an exterior window of any slope. Light wells can be assigned to both rectangular and triangular exterior windows, but they should not be assigned to interior windows. Note that the sides of the light well can be sloped and the bottom of the light well can be any shape, not just rectangular.

##### 1.15.11.1.2 Field: Height of Well

The distance from the bottom of the skylight to the bottom of the well. If the skylight and well bottom are not coplanar, this is the distance from the center of the bottom of the skylight to center of the bottom of the well. See Figure 1.87.

##### 1.15.11.1.3 Field: Perimeter of Bottom of Well

The perimeter of the bottom opening of the well. See Figure 1.87.

##### 1.15.11.1.4 Field: Area of Bottom of Well

The area of the bottom opening of the well. A warning will be issued if this area is less than the area of the skylight, including frame if present. See Figure 1.87.

### 1.15.11.1.5 Field: Visible Reflectance of Well Walls

The visible reflectance of the side walls of the well. If the walls do not all have the same reflectance, an area-weighted average value can be used. This is the well-wall reflectance expressed as a fraction.

An IDF example:

```
DaylightingDevice:LightWell, ! The well is 60% reflecting, is 1.2m high and has a 2.5m x 5.5m bottom
opening.
Skylight-1, !- Name of Exterior Window that this Light Well Applies To
1.2,      !- Height of Well(m)
16.0,     !- Perimeter of Bottom of Well (m)
13.75,    !- Area of Bottom of Well (m2)
0.60;     !- Visible Reflectance of Well Walls
```

## 1.15.12 Daylighting Modeling Options

The following table shows what input objects/fields to use to model different daylighting options. It also gives the name of an example input, if available, that demonstrates the option.

Table 1.32: Daylighting Modeling Options

Option	Object/Field or Output Variable	Input File
Allow a thermal zone to be daylit	Daylighting:Controls, Daylighting:ReferencePoint	PurchAirWithDaylighting.idf, DElight-Detailed-Comparison.idf
Specify visible transmittance of the glazing	WindowMaterial:Glazing	PurchAirWithDaylighting.idf
Specify the visible transmittance of a shading device	WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind	PurchAirWindowBlind.idf
Use a shading device to control glare	WindowMaterial:Shade or WindowMaterial:Blind; WindowShadingControl*	PurchAirWindowBlind.idf
Use electrochromic glazing to control glare	WindowShadingControl/Shading Type = SwitchableGlazing, Shading Control Type = On If High Glare, Glare Control Is Active = Yes*	PurchAirWithDaylighting.idf
Adjust electrochromic glazing to just meet daylighting illuminance setpoint	WindowShadingControl/Shading Type = SwitchableGlazing, Shading Control Type = MeetDaylightIlluminanceSetpoint*	
Print an illuminance map	Daylighting:Illuminance Map*	
Control electric lighting response to daylight illuminance level	Daylighting:Controls/Lighting Control Type = Continuous, Stepped or Continuous/Off, plus other fields; or ...	PurchAirWithDaylighting.idf, DElight-Detailed-Comparison.idf
Add a light shelf (with Daylighting:Controls)	DaylightingDevice:Shelf *	DaylightingDeviceShelf.idf
Add a light shelf (with Daylighting:Controls)	Daylighting:Controls using DElight	DElightCFSLightShelf.idf
Add a light pipe	DaylightingDevice:Tubular *	DaylightingDeviceTubular.idf
Model a skylight having a light well	DaylightingDevice:LightWell *	
Model daylighting through double facade	See “Double Facades: Daylighting through Interior Windows”*	PurchAirWithDoubleFacadeDaylighting.idf
Add diffusing (translucent) glass	WindowMaterial:Glazing/Solar Diffusing = Yes*	
Model complex fenestration	Daylighting:Controls using DElight	DElightCFSWindow.idf
Get a radiosity-based interior light inter-reflection calculation	Daylighting:Controls using DElight	DElight-Detailed-Comparison.idf
Find effect on daylighting of solar reflected from overhangs, neighboring buildings, etc.	Building/SolarDistribution uses “withReflections” option	

Table 1.32: Daylighting Modeling Options

Option	Object/Field or Output Variable	Input File
Find visible transmittance effect of dirt on window	WindowMaterial:Glazing/Dirt Correction Factor for Solar and Visible Transmittance*	

\*Used only with [Daylighting:Controls](#) with the SplitFlux Daylighting Method.

[1] Formerly, only the exterior windows in a zone could provide daylight to that zone.

## 1.16 Group – Exterior Energy Use Equipment

To facilitate the reporting of exterior consumption (to the building's heat balance/loads considerations), several objects have been included. The consumption related to these items will appear on meters specific to the items.

### 1.16.1 Exterior:Lights

#### 1.16.1.1 Inputs

##### 1.16.1.1.1 Field: Name

This descriptive name allows the values of exterior lights consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:Lights statements.

##### 1.16.1.1.2 Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

##### 1.16.1.1.3 Field: Design Level

This field (in Watts) is typically used to represent the maximum electrical input to exterior lighting fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

##### 1.16.1.1.4 Field: Control Option

This field is used to determine how the exterior lights are controlled. There are currently two options, ‘ScheduleNameOnly’ and ‘AstronomicalClock.’ If this field is omitted or left blank then the program will default to Schedule Name Only mode. The ‘ScheduleNameOnly’ mode dictates that the exterior lights always follow the schedule named in the field above. The ‘AstronomicalClock’ mode dictates that despite what the schedule indicates, the exterior lights will not run when the sun is up. Using the Astronomical Clock mode makes it simple to model exterior lights that are controlled by a photocell or other controller that ensures that outdoor lights will not run during the daytime. However, the Astronomical Clock control works off of the position of the sun and therefore does not operate exactly like a photocell. During the night, the schedule values are still applied in the usual way.

### 1.16.1.1.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Grounds Lights”, “Facade Lights”, etc. A new meter for reporting is created for each unique subcategory (ref: **Output:Meter** objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary table named EA2-4/5 Performance Rating Method Compliance.

An IDF Example:

```
Exterior:Lights,
  OutsideLights,      !- Name
  ON,                !- SCHEDULE Name
  1000,              !- Design Level
  AstronomicalClock, !- Control Option
  Grounds Lights;   !- End-Use Subcategory
```

### 1.16.1.2 Outputs

Output for exterior lights appears in three possible places. It will appear on two meters (Electricity:Facility and ExteriorLights:Electricity) as well as in its own designated value in the standard output file.

- Zone,Average,Exterior Lights Electricity Rate [W]
- Zone,Sum,Exterior Lights Electricity Energy [J]

#### 1.16.1.2.1 Exterior Lights Electricity Rate [W]

#### 1.16.1.2.2 Exterior Lights Electricity Energy [J]

These are the electric power and energy consumed by the exterior lights.

## 1.16.2 Exterior:FuelEquipment

### 1.16.2.1 Inputs

#### 1.16.2.1.1 Field: Name

This descriptive name allows the values of exterior equipment consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other **Exterior:FuelEquipment** or **Exterior:WaterEquipment** statements.

#### 1.16.2.1.2 Field: Fuel Use Type

This field designates the appropriate meter for the exterior fuel equipment. Valid fuel types are: Electricity, NaturalGas, Propane, FuelOilNo1, FuelOilNo2, Diesel, Gasoline, Coal, Steam, **DistrictHeating**, **DistrictCooling**, OtherFuel1 and OtherFuel2. The fuel type triggers the application of consumption amounts to the appropriate energy meters.

#### 1.16.2.1.3 Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

#### 1.16.2.1.4 Field: Design Level

This field (Watts) is typically used to represent the maximum input to exterior fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

#### 1.16.2.1.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Fountains”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the “General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table.

IDF Examples:

```
Exterior:FuelEquipment,OutsideGasEq,NaturalGas,ON,1000;
Exterior:FuelEquipment,OutsideCoalEq,Coal,ON,1000;
Exterior:FuelEquipment,OutsideFuelOilNo1Eq,FuelOilNo1,ON,1000;
Exterior:FuelEquipment,OutsideFuelOilNo2Eq,FuelOilNo2,ON,1000;
Exterior:FuelEquipment,OutsideLPGEq,Propane,ON,1000;
```

### 1.16.3 Exterior:WaterEquipment

#### 1.16.3.1 Inputs

##### 1.16.3.1.1 Field: Name

This descriptive name allows the values of exterior equipment consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other [Exterior:FuelEquipment](#) or [Exterior:WaterEquipment](#) statements.

##### 1.16.3.1.2 Field: FuelUseType

For [Exterior:WaterEquipment](#), only “Water” is current allowed for this field.

##### 1.16.3.1.3 Field: Schedule Name

A schedule will allow the exterior water consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

##### 1.16.3.1.4 Field: Design Level

This field (in m<sup>3</sup>/s) is typically used to represent the maximum volumetric flow for water fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the exterior water equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

##### 1.16.3.1.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Landscaping”, etc. A new meter for reporting is created for each unique subcategory (ref: [Output:Meter](#) objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the

“General” end-use subcategory. Any text may be used here to categorize the end-uses in the ABUPS End Uses by Subcategory table and in the LEED Summary EAp2-4/5 Performance Rating Method Compliance table.

IDF Example:

```
Exterior:WaterEquipment,
  OutsideWaterEq,      !- Name
  Water,               !- Fuel Use Type
  ON,                  !- Schedule Name
  1000.0,              !- Design Level
  General;             !- End-Use Subcategory
```

### 1.16.3.2 Outputs

Output for exterior equipment consumption appears in three possible places. It will appear on two meters (Fuel Type:Facility and ExteriorEquipment:Fuel Type) as well as in its own designated value in the standard output file, Exterior Equipment Fuel Type Energy. Consumption also appears on any user-defined end-use subcategory meters, i.e., End-Use Subcategory:ExteriorEquipment:Fuel Type. All outputs are in [J] except water consumption which is in [m<sup>3</sup>]. There are also rate versions

- Zone, Average, Exterior Equipment Fuel Rate [W]
- Zone,Sum, Exterior Equipment Electricity Energy [J]
- Zone,Sum, Exterior Equipment Gas Energy [J]
- Zone,Average, Exterior Equipment Water Volume Flow Rate [m<sup>3</sup>/s]
- Zone,Sum, Exterior Equipment Water Volume [m<sup>3</sup>]
- Zone,Sum, Exterior Equipment Mains Water Volume [m<sup>3</sup>]
- Zone,Sum, Exterior Equipment Coal Energy [J]
- Zone,Sum, Exterior Equipment FuelOilNo1 Energy [J]
- Zone,Sum, Exterior Equipment FuelOilNo2 Energy [J]
- Zone,Sum, Exterior Equipment Propane Energy [J]
- Zone,Sum, Exterior Equipment Gasoline Energy [J]
- Zone,Sum, Exterior Equipment Diesel Energy [J]
- Zone,Sum, Exterior Equipment Steam Energy [J]
- Zone,Sum, Exterior Equipment OtherFuel1 Energy [J]
- Zone,Sum, Exterior Equipment OtherFuel2 Energy [J]
- Zone,Sum, Exterior Equipment District Heating Energy [J]
- Zone,Sum, Exterior Equipment District Cooling Energy [J]

#### 1.16.3.2.1 Exterior Equipment Fuel Rate [W]

### 1.16.3.2.2 Exterior Equipment Fuel Type Energy [J]

These are the fuel consumption rate and energy for the exterior equipment.

### 1.16.3.2.3 Exterior Equipment Water Volume Flow Rate [m<sup>3</sup>/s]

### 1.16.3.2.4 Exterior Equipment Water Volume [m<sup>3</sup>]

These are the water consumption rate and volume for the exterior equipment.

### 1.16.3.2.5 Exterior Equipment Mains Water Volume [m<sup>3</sup>]

This is the water volume drawn for the mains water service to serve the exterior equipment.

## 1.17 Group – Airflow

An important characteristic of energy consumption in buildings is the airflow between zones and airflow due to natural ventilation (e.g., open windows) or mechanically-induced ventilation (e.g., exhaust air fans). This group of objects describes those elements.

The AirflowNetwork model can also be used to model infiltration and mixing (zone-to-zone air flow) with or without the HVAC air distribution system operating (see Group – Airflow Network).

### 1.17.1 ZoneInfiltration:DesignFlowRate

Infiltration is the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. The basic equation used to calculate infiltration with this object is:

$$\text{Infiltration} = (\text{I}_{\text{design}}) (\text{F}_{\text{schedule}}) [\text{A} + \text{B} |(\text{T}_{\text{zone}} - \text{T}_{\text{odb}})| + \text{C} (\text{WindSpeed}) + \text{D} (\text{Windspeed}^2)] \quad (1.38)$$

More advanced infiltration calculations are possible using the EnergyPlus AirflowNetwork model for natural infiltration driven by wind and/or by forced air. Infiltration described by the equation shown above is entered into EnergyPlus using the following syntax. Exfiltration (the leakage of zone air to the outside) is generally handled better as zone exhaust air in the zone equipment description. The equation must always yield a non-negative results; negative values are set to 0.0.

The question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the infiltration situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The EnergyPlus defaults are 1,0,0,0 which give a constant volume flow of infiltration under all conditions.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5 mph) windspeed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) windspeed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (windspeed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A windspeed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

“Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions.”

The source of the DOE-2 defaults is based on examining the infiltration relationships described in the ASHRAE Handbook of Fundamentals.

The EnergyPlus example files use all of the above, the BLAST defaults in some (e.g., GeometryTest), the DOE-2 defaults in some (e.g., 5ZoneAirCooled), and the EnergyPlus defaults in some (e.g., LgOffVAVDetCoil).

The local outdoor dry-bulb temperature used in the above basic equation ( $T_{odb}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is given in the section of “Local Outdoor Air Temperature Calculation” in the Engineering Reference.

The local outdoor wind speed used in the above basic equation (WindSpeed) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is given in the section of “Local Wind Speed Calculation” in the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the **Site:HeightVariation** is equal to 0.0. The local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0 the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more infiltration objects can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

### 1.17.1.1 Inputs

#### 1.17.1.1.1 Field: Name

The name of the ZoneInfiltration:DesignFlowRate object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.17.1.1.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or **ZoneList** (ref: ZoneList) and attaches a particular infiltration statement to a thermal zone or set of thermal zones in the building. When the **ZoneList** option is used then this infiltration definition is applied to each of the zones in the zone list effecting a global definition for the amount of infiltration flow rate in the zone. The Zonelist option can be used effectively with the flow/area, flow/exteriorarea, flow/exteriorwallarea, or airchanges/hour of the Design Flow Rate Calculation Method.

The name of the actual infiltration object becomes <Zone Name> <ZoneInfiltration:DesignFlowRate Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.17.1.1.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate ( $I_{design}$ ) (see Design Flow Rate Calculation Method field and related subsequent fields). This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.17.1.1.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The flow per Zone Area field should be filled).

- Flow/ExteriorArea

With this choice, the method used will be a factor per exterior surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- Flow/ExteriorWallArea

With this choice, the method used will be a factor per exterior wall surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### 1.17.1.1.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $\text{m}^3/\text{s}$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate (noted as  $I_{design}$  in the above equation) is the maximum amount of infiltration expected at design conditions. The design value is modified by the schedule fraction (see Field:Schedule Name) and user specified coefficients (see “coefficient” fields below). The resulting volume flow rate is converted to mass flow using the current outdoor air density at each time step.

#### 1.17.1.1.6 Field: Flow per Zone Floor Area

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Zone Area to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be “Flow/Area”.

#### 1.17.1.1.7 Field: Flow per Exterior Surface Area

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Exterior Surface Area in the Zone to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be “Flow/ExteriorArea” or “Flow/ExteriorWallArea”.

#### 1.17.1.1.8 Field: Air Changes per Hour

This factor is used, along with the Zone Volume to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be “AirChanges/Hour”.

### 1.17.1.1.9 Field: Constant Term Coefficient

This number is the “A” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

### 1.17.1.1.10 Field: Temperature Term Coefficient

This number is the “B” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

### 1.17.1.1.11 Field: Velocity Term Coefficient

This number is the “C” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

### 1.17.1.1.12 Field: Velocity Squared Term Coefficient

This number is the “D” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s<sup>2</sup>/m<sup>2</sup>.

```

## 1.17.2 ZoneInfiltration:EffectiveLeakageArea

ZoneInfiltration:EffectiveLeakageArea model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This model is based on work by Sherman and Grimsrud (1980) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the effective leakage area model is:

$$\text{Infiltration} = (F_{\text{Schedule}}) \frac{A_L}{1000} \sqrt{C_s \Delta T + C_w (\text{WindSpeed})^2} \quad (1.39)$$

where  $\Delta T$  is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the “EffectiveLeakageArea” model are not interchangeable with the similarly named coefficients in the “FlowCoefficient” model (see [ZoneInfiltration:FlowCoefficient](#) object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

### 1.17.2.1 Inputs

#### 1.17.2.1.1 Field: Name

The name of the ZoneInfiltration:EffectiveLeakageArea object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.17.2.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

#### 1.17.2.1.3 Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as  $F_{\text{schedule}}$  in the above equation.

#### 1.17.2.1.4 Field: Effective Air Leakage Area

This field is the effective air leakage area, in  $\text{cm}^2$ , at 4 Pa. This is the value  $A_L$  in the equation above. Effective leakage area data can be obtained from a whole-building pressure test (eg. blower door test). ASHRAE Handbook of Fundamentals also lists typical values component leakage areas for low-rise residential (e.g. Table 1.2 in Chapter 26 of HoF 2001). The value should correspond to a pressure difference of 4 Pa.

#### 1.17.2.1.5 Field: Stack Coefficient

This field is the value of the stack coefficient,  $C_s$  in the equation above. The coefficient has units of  $(\text{L}/\text{s})^2/(\text{cm}^4 \cdot \text{K})$ . Values for the “Basic Model Stack Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

One story house	Two story house	Three story house
0.000145	0.000290	0.000435

### 1.17.2.1.6 Field: Wind Coefficient

This field is the value of the wind coefficient,  $C_w$  in the equation above. The coefficient has units of  $(\text{L}/\text{s})^2/(\text{cm}^4 \cdot (\text{m}/\text{s})^2)$ . Values for the “Basic Model Wind Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 chapter 27; 2001, Chapter 26) depend on the type of shelter and are listed in the following tables.

Shelter class	One story house	Two story house	Three story house
1	0.000319	0.000420	0.000494
2	0.000246	0.000325	0.000382
3	0.000174	0.000231	0.000271
4	0.000104	0.000137	0.000161
5	0.000032	0.000042	0.000049

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

An example IDF object is

```
ZoneInfiltration:EffectiveLeakageArea,
  LIVING ZONE Infil 1,      !- Name
  LIVING ZONE,              !- Zone Name
  INF-SCHED,                !- Schedule Name
  500.0,                   !- Effective Air Leakage Area
  0.000145,                !- Stack Coefficient
  0.000174 ;               !- Wind Coefficient
```

### 1.17.3 ZoneInfiltration:FlowCoefficient

ZoneInfiltration:FlowCoefficient model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This reformulated model is based on the AIM-2 model by Walker and Wilson (1998) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the flow coefficient model is:

$$\text{Infiltration} = (F_{\text{Schedule}}) \sqrt{(c C_s \Delta T^n)^2 + (c C_w (s * \text{WindSpeed})^{2n})^2} \quad (1.40)$$

Where  $\Delta T$  is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the “Flow Coefficient” model are not interchangeable with the similarly named coefficients in the “Effective Leakage Area” model (see [ZoneInfiltration:EffectiveLeakageArea](#) object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

### 1.17.3.1 Inputs

#### 1.17.3.1.1 Field: Name

The name of the ZoneInfiltration:FlowCoefficient object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.17.3.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

#### 1.17.3.1.3 Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.17.3.1.4 Field: Flow Coefficient

This field is the flow coefficient in  $\text{m}^3/(\text{s} \cdot \text{Pa}^n)$ . This is the value  $c$  in the equation above. The flow coefficient can be determined from the effective leakage area and whole-building pressure tests (eg. blower door test).

#### 1.17.3.1.5 Field: Stack Coefficient

This field is the value of the stack coefficient,  $C_s$  in the equation above. The coefficient has units of  $(\text{Pa}/\text{K})^n$ . Values for the “Enhanced Model Stack Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
With Flue	0.069	0.089	0.107
No Flue	0.054	0.078	0.098

#### 1.17.3.1.6 Field: Pressure Exponent

This field is the value of the pressure exponent,  $n$  in the equation above. The pressure exponent generally lies between 0.6 and 0.7 with a typical value of  $n = 0.67$  for the enhanced model.

#### 1.17.3.1.7 Field: Wind Coefficient

This field is the value of the wind coefficient,  $C_w$  in the equation above. The coefficient has units of  $(\text{Pa} \cdot \text{s}^2/\text{m}^2)^n$ . Values for the “Enhanced Model Wind Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
Basement/slab; With Flue	0.142	0.156	0.167
Basement/slab; No Flue	0.156	0.170	0.170

	One story house	Two story house	Three story house
Crawlspac; With Flue	0.128	0.142	0.154
Crawlspac; No Flue	0.128	0.142	0.151

#### 1.17.3.1.8 Field: Shelter Factor

This field is the value of the wind coefficient,  $s$  in the equation above. The coefficient is dimensionless. Values for the “Enhanced Model Shelter Factor” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

Shelter class	No Flue	One story house with flue	Two story house with flue	Three story house with flue
1	1.00	1.10	1.07	1.06
2	0.90	1.02	0.98	0.97
3	0.70	0.86	0.81	0.79
4	0.50	0.70	0.64	0.61
5	0.30	0.54	0.47	0.43

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

An Example IDF object is:

```
ZoneInfiltration:FlowCoefficient,
  LIVING ZONE Infil 1,      !- Name
  LIVING ZONE,              !- Zone Name
  INF-SCHED,               !- Schedule Name
  0.05,                    !- Flow Coefficient
  0.089,                   !- Stack Coefficient
  0.67,                    !- Pressure Exponent

#### 1.17.3.2 Outputs

Zone Infiltration objects have output variables for individual objects and for zone totals.

Object level outputs include:

- HVAC,Sum,Infiltration Sensible Heat Loss Energy [J]
- HVAC,Sum,Infiltration Sensible Heat Gain Energy [J]
- HVAC,Sum,Infiltration Latent Heat Loss Energy [J]
- HVAC,Sum,Infiltration Latent Heat Gain Energy [J]

- HVAC,Sum,Infiltration Total Heat Loss Energy [J]
- HVAC,Sum,Infiltration Total Heat Gain Energy [J]
- HVAC,Average,Infiltration Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Infiltration Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Infiltration Current Density Volume [m<sup>3</sup>]
- HVAC,Sum,Infiltration Standard Density Volume [m<sup>3</sup>]
- HVAC,Sum,Infiltration Mass [kg]
- HVAC,Sum,Infiltration Mass Flow Rate [kg/s]
- HVAC,Average,Infiltration Air Change Rate [ach]

Zone level outputs include:

- HVAC,Sum,Zone Infiltration Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Infiltration Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Infiltration Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Infiltration Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Infiltration Total Heat Loss Energy [J]
- HVAC,Sum,Zone Infiltration Total Heat Gain Energy [J]
- HVAC,Average,Zone Infiltration Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Zone Infiltration Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Infiltration Current Density Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Infiltration Standard Density Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Infiltration Mass [kg]
- HVAC,Sum,Zone Infiltration Mass Flow Rate [kg/s]
- HVAC,Average,Zone Infiltration Air Change Rate [ach]

Note: If ZoneInfiltration:<sup>\*</sup> objects and ZoneAirBalance:OutdoorAir (with Air Balance Method = Quadrature) objects reference the same Zone Name, the above infiltration output variables will not be reported for that zone. Instead, output variables for zone outdoor air flow will be reported by the corresponding ZoneAirBalance:OutdoorAir object.

#### **1.17.3.2.1 Zone Infiltration Sensible Heat Loss Energy [J]**

The sensible (temperature) heat loss that occurs when the infiltration air temperature (outdoor) < zone air temperature.

**1.17.3.2.2 Zone Infiltration Sensible Heat Gain Energy [J]**

The sensible (temperature) heat gain that occurs when the infiltration air temperature (outdoor)  $\geq$  zone air temperature.

**1.17.3.2.3 Zone Infiltration Latent Heat Loss Energy [J]**

The latent heat loss that occurs when the infiltration air humidity ratio (outdoor)  $<$  zone air humidity ratio.

**1.17.3.2.4 Zone Infiltration Latent Heat Gain Energy [J]**

The latent heat gain that occurs when the infiltration air humidity ratio (outdoor)  $\geq$  zone air humidity ratio.

**1.17.3.2.5 Zone Infiltration Total Heat Loss Energy [J]**

The total heat loss that occurs when the sum of Zone Infiltration Sensible Heat Gain Energy and Zone Infiltration Latent Heat Gain Energy  $<$  the sum of Zone Infiltration Sensible Heat Loss Energy and Zone Infiltration Latent Heat Loss Energy.

**1.17.3.2.6 Zone Infiltration Total Heat Gain Energy [J]**

The total heat gain that occurs when the sum of Zone Infiltration Sensible Heat Gain Energy and Zone Infiltration Latent Heat Gain Energy  $\geq$  the sum of Zone Infiltration Sensible Heat Loss Energy and Zone Infiltration Latent Heat Loss Energy.

**1.17.3.2.7 Zone Infiltration Current Density Volume [m<sup>3</sup>]****1.17.3.2.8 Zone Infiltration Current Density Volume Flow Rate [m<sup>3</sup>/s]**

These outputs are the total volume and volume flow rate of infiltration air based on the current density of zone air.

**1.17.3.2.9 Zone Infiltration Standard Density Volume [m<sup>3</sup>]****1.17.3.2.10 Zone Infiltration Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

These outputs are the total volume and volume flow rate of infiltration air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

**1.17.3.2.11 Zone Infiltration Mass [kg]**

The mass flow of the Infiltration air.

**1.17.3.2.12 Zone Infiltration Mass Flow Rate [kg/s]**

The mass flow rate of the Infiltration air.

**1.17.3.2.13 Zone Infiltration Air Change Rate [ach]**

The rate of infiltration in air changes per hour.

### 1.17.4 ZoneVentilation:DesignFlowRate

Ventilation is the purposeful flow of air from the outdoor environment directly into a thermal zone in order to provide some amount of non-mechanical cooling. Ventilation, as specified by the input syntax for the ZoneVentilation:DesignFlowRate object, is intended to model “simple” ventilation as opposed to the more detailed ventilation investigations that can be performed with the AirflowNetwork model or with air systems that have outdoor air mixers. Zone ventilation, as specified via this input object, can be controlled by a schedule and through the specification of minimum, maximum and delta temperatures as described below. The temperatures can be either single constant values for the entire simulation or schedules which can vary over time. As with infiltration, the actual flow rate of ventilation air can be modified by the temperature difference between the inside and outside environment and the wind speed. The basic equation used to calculate ventilation with this model is:

$$\text{Ventilation} = (V_{\text{design}}) (F_{\text{schedule}}) [A + B |T_{\text{zone}} - T_{\text{odb}}| + C (\text{WindSpeed}) + D (\text{WindSpeed}^2)] \quad (1.41)$$

Similar to infiltration, the question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the ventilation situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The EnergyPlus defaults are 1,0,0,0 which give a constant volume flow of ventilation under all conditions. The following discussion is duplicated from the infiltration design flow rate object. The equation must always yield a non-negative results; negative values are set to 0.0.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5 mph) windspeed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) windspeed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (windspeed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A windspeed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

“Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions.”

The source of the DOE-2 defaults is based on examining the *infiltration* relationships described in the ASHRAE Handbook of Fundamentals.

The local outdoor dry-bulb temperature used in the above basic equation ( $T_{\text{odb}}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is described in the “Local Outdoor Air Temperature Calculation” section of the Engineering Reference.

The local outdoor wind speed used in the above basic equation (WindSpeed) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is described in the “Local Wind Speed Calculation” section of the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation object is equal to 0.0, the local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0, the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more ventilation objects (i.e., ZoneVentilation:DesignFlowRate and/or ZoneVentilation:WindandStackOpen) can be defined for each zone, and the resulting ventilation rate for the zone will simply be the summation of the flow rates specified by the ventilation objects.

More advanced ventilation calculations are possible using the EnergyPlus AirflowNetwork model.

### 1.17.4.1 Inputs

#### 1.17.4.1.1 Field: Name

The name of the ZoneVentilation:DesignFlowRate object.

#### 1.17.4.1.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or **ZoneList** (ref: **ZoneList**) and attaches a particular ventilation statement to a thermal zone or set of thermal zones in the building. When the **ZoneList** option is used then this ventilation definition is applied to each of the zones in the zone list effecting a global definition for the amount of infiltration flow rate in the zone. The Zonelist option can be used effectively with the flow/area, flow/person, or airchanges/hour of the Design Flow Rate Calculation Method.

The name of the actual ventilation object becomes <Zone Name> <ZoneVentilation:DesignFlowRate Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.17.4.1.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate ( $V_{design}$ ) (see Design Flow Rate Calculation Method field and related subsequent fields). This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.17.4.1.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### 1.17.4.1.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $\text{m}^3/\text{s}$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate (noted as  $V_{design}$  in the above equation) is the maximum amount of ventilation expected at design conditions. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

#### **1.17.4.1.6 Field: Flow Rate per Zone Floor Area**

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/area”.

#### **1.17.4.1.7 Field: Flow Rate per Person**

This factor ( $\text{m}^3/\text{s}\cdot\text{person}$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/person”.

#### **1.17.4.1.8 Field: Air Changes per Hour**

With this choice, the method used will be the number of air changes per hour for the ventilation amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### **1.17.4.1.9 Field: Ventilation Type**

This alpha character string defines the type of ventilation as one of the following options: Natural, Exhaust, Intake, or Balanced. Natural ventilation is assumed to be air movement/exchange as a result of openings in the building façade and will not consume any fan energy. Values for fan pressure and efficiency for natural ventilation are ignored. For either Exhaust or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaust ventilation, the conditions of the air entering the space are assumed to be equivalent to outside air conditions. For Intake and Balanced ventilation, an appropriate amount of fan heat is added to the entering air stream. For Balanced ventilation, both an intake fan and an exhaust fan are assumed to co-exist, both having the same flow rate and power consumption (using the entered values for fan pressure rise and fan total efficiency). Thus, the fan electric consumption for Balanced ventilation is twice that for the Exhaust or Intake ventilation types which employ only a single fan.

#### **1.17.4.1.10 Field: Fan Pressure Rise**

This is the pressure rise experienced across the fan in Pascals ( $\text{N}/\text{m}^2$ ). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

#### **1.17.4.1.11 Field: Fan Total Efficiency**

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1.”

#### **1.17.4.1.12 Field: Constant Term Coefficient**

This number is the “A” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

#### **1.17.4.1.13 Field: Temperature Term Coefficient**

This number is the “B” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the

temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

#### 1.17.4.1.14 Field: Velocity Term Coefficient

This number is the “C” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

#### 1.17.4.1.15 Field: Velocity Squared Term Coefficient

This number is the “D” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s<sup>2</sup>/m<sup>2</sup>.

#### 1.17.4.1.16 Field: Minimum Indoor Temperature

This is the indoor temperature (in Celsius) below which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, ventilation is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then ventilation is automatically turned off.

#### 1.17.4.1.17 Field: Minimum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the minimum indoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Indoor Temperature field. If the user enters a valid schedule name, the minimum temperature values specified in this schedule will override the constant value specified in the Minimum Indoor Temperature field.

#### 1.17.4.1.18 Field: Maximum Indoor Temperature

This is the indoor temperature (in Celsius) above which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 28°C, ventilation is assumed to be available if the zone air temperature is below 28°C. If the zone air temperature increases to 28°C, then ventilation is automatically turned off.

#### 1.17.4.1.19 Field: Maximum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the maximum indoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Indoor Temperature field. If the user enters a valid schedule name, the maximum temperature values specified in this schedule will override the constant value specified in the Maximum Indoor Temperature field.

#### 1.17.4.1.20 Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff. The minimum value for this field is -100.0°C and

the default value is also -100.0°C if the field is left blank. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off.

The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

Thus, if a large negative number is input for DeltaTemperature, the ventilation can be kept on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

#### **1.17.4.1.21 Field: Delta Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff as a function of time. The minimum temperature difference value in the schedule can be -100°C. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will override the constant value specified in the Delta Temperature field.

#### **1.17.4.1.22 Field: Minimum Outdoor Temperature**

This is the outdoor temperature (in Celsius) below which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

#### **1.17.4.1.23 Field: Minimum Outdoor Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Minimum Outdoor Temperature field.

#### **1.17.4.1.24 Field: Maximum Outdoor Temperature**

This is the outdoor temperature (in Celsius) above which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

#### **1.17.4.1.25 Field: Maximum Outdoor Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Maximum Outdoor Temperature field.

#### 1.17.4.1.26 Field: Maximum Wind Speed

This is the wind speed (m/s) above which ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid chaos in a space (papers blowing around, etc.).

Two IDF examples are provided below:

### 1.17.5 ZoneVentilation:WindandStackOpenArea

For this model, the ventilation air flow rate is a function of wind speed and thermal stack effect, along with the area of the opening being modeled. This object can be used alone or in combination with [ZoneVentilation:DesignFlowRate](#) objects. This model is intended for simplified ventilation calculations as opposed to the more detailed ventilation investigations that can be performed with the AirflowNetwork model. Using the “Wind and Stack with Open Area” model, the natural ventilation flow rate can be controlled by a multiplier fraction schedule applied to the user-defined opening area and through the specification of minimum, maximum and delta temperatures. The temperatures can be either single constant values for the entire simulation or schedules which can vary over time. The equation used to calculate the ventilation rate driven by wind is:

$$Q_w = C_w A_{opening} F_{schedule} V \quad (1.42)$$

where,

- $Q_w$  = Volumetric air flow rate driven by wind [ $\text{m}^3/\text{s}$ ]
- $C_w$  = Opening effectiveness [dimensionless]
- $A_{opening}$  = Opening area [ $\text{m}^2$ ]
- $F_{schedule}$  = Open area fraction [user-defined schedule value, dimensionless]
- $V$  = Local wind speed [ $\text{m}/\text{s}$ ]

The equation used to calculate the ventilation rate due to stack effect is:

$$Q_s = C_D A_{opening} F_{schedule} \sqrt{2g\Delta H_{NPL}(|T_{zone} - T_{odb}|/T_{zone})} \quad (1.43)$$

where,

- $Q_s$  = Volumetric air flow rate due to stack effect [ $\text{m}^3/\text{s}$ ]
- $C_D$  = Discharge coefficient for opening [dimensionless]
- $A_{opening}$  = Opening area [ $\text{m}^2$ ]
- $F_{schedule}$  = Open area fraction [user-defined schedule value, dimensionless]
- $\Delta H_{NPL}$  = Height from midpoint of lower opening to the neutral pressure level [m].

Estimation of this value is difficult; refer to Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals for guidance.

- $T_{zone}$  = Zone air dry-bulb temperature [K]
- $T_{odb}$  = Local outdoor air dry-bulb temperature [K]

The total ventilation rate calculated by this model is the quadrature sum of the wind and stack air flow components:

$$Ventilation_{WindAndStack} = \sqrt{Q_s^2 + Q_w^2} \quad (1.44)$$

The local outdoor air dry-bulb temperature used in the stack effect equation ( $T_{odb}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor air dry-bulb temperature calculation procedure is described in the “Local Outdoor Air Temperature Calculation” section of the Engineering Reference.

The local outdoor wind speed used in the above wind-driven equation ( $V$ ) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is described in the “Local Wind Speed Calculation” section of the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the **Site:HeightVariation** object is equal to 0.0, the local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0, the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more ventilation objects (i.e., **ZoneVentilation:DesignFlowRate** and/or **ZoneVentilation:WindandStackOpen**) can be defined for each zone, and the resulting ventilation rate for the zone will simply be the summation of the flow rates specified by the ventilation objects.

More advanced ventilation calculations are possible using the EnergyPlus AirflowNetwork model.

### 1.17.5.1 Inputs

#### 1.17.5.1.1 Field: Name

The name of the **ZoneVentilation:WindandStackOpenArea** object.

#### 1.17.5.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular ventilation statement to a thermal zone in the building.

#### 1.17.5.1.3 Field: Opening Area

This is the opening area exposed to outdoors ( $\text{m}^2$ ) in a zone.

#### 1.17.5.1.4 Field: Opening Area Fraction Schedule Name

This field is the name of the schedule (ref: Schedule) which modifies the Opening Area value (see previous field). The schedule values must be any positive number between 0 and 1 as a fraction. The actual opening area in a zone for a particular simulation time step is defined as the product of the Opening Area input field and the value specified by the schedule named in this input field.

#### 1.17.5.1.5 Field: Opening Effectiveness

This field is the opening effectiveness ( $C_w$ ). The value must be between 0.0 and 1.0 or the value can be autocalculated. If a real value is input, that constant value will be used in the calculations. Otherwise, this field can be left blank (default = Autocalculate) or the user can input **Autocalculate**. Based on recommended values provided in Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals,  $C_w = 0.55$  for perpendicular winds and  $C_w = 0.3$  for diagonal winds. For Autocalculate, any angles between perpendicular and diagonal are linearly interpolated between 0.3 and 0.55 by the model.

#### 1.17.5.1.6 Field: Effective Angle

This is the angle in degrees counting from the North clockwise to the opening outward normal. The value must be between 0 and 360, with the default being 0 if this input field is left blank. The Effective Angle is 0 if the opening outward normal faces North, 90 if faces East, 180 if faces South, and 270 if faces West. The value is fixed and independent of coordinate system defined in the **GlobalGeometryRules** object. This input field value is used to calculate the angle between the wind direction and the opening outward normal to determine the opening effectiveness values when the input field Opening Effectiveness = Autocalculate.

#### 1.17.5.1.7 Field: Height Difference

This is the height difference between the midpoint of the lower opening and the neutral pressure level in meters. This value is a required user input.

Note: Estimation of the height difference is difficult for natural ventilated buildings. Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals may provide guidance for estimating the height difference.

#### 1.17.5.1.8 Field: Discharge Coefficient for Opening

This is the discharge coefficient for the opening ( $C_D$ ). The value must be between 0.0 and 1.0, or the value can be autocalculated. If a real value is input, that constant value will be used in the calculations. Otherwise, this field can be left blank (default = Autocalculate) or the user can input **Autocalculate**. For Autocalculate, the program will determine the discharge coefficient based on the following equation:

$$C_D = 0.40 + 0.0045 |T_{zone} - T_{odb}| \quad (1.45)$$

#### 1.17.5.1.9 Field: Minimum Indoor Temperature

This is the indoor temperature (in Celsius) below which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, ventilation is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then ventilation is automatically turned off.

#### 1.17.5.1.10 Field: Minimum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the minimum indoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Indoor Temperature field. If the user enters a valid schedule name, the minimum temperature values specified in this schedule will override the constant value specified in the Minimum Indoor Temperature field.

#### 1.17.5.1.11 Field: Maximum Indoor Temperature

This is the indoor temperature (in Celsius) above which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 28°C, ventilation is assumed to be available if the zone air temperature is below 28°C. If the zone air temperature increases to 28°C, then ventilation is automatically turned off.

#### **1.17.5.1.12 Field: Maximum Indoor Temperature Schedule Name**

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the maximum indoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Indoor Temperature field. If the user enters a valid schedule name, the maximum temperature values specified in this schedule will override the constant value specified in the Maximum Indoor Temperature field.

#### **1.17.5.1.13 Field: Delta Temperature**

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff. The minimum value for this field is -100.0°C and the default value is also -100.0°C if the field is left blank. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off.

The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

Thus, if a large negative number is input for DeltaTemperature, the ventilation can be kept on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

#### **1.17.5.1.14 Field: Delta Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff as a function of time. The minimum temperature difference value in the schedule can be -100°C. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will override the constant value specified in the Delta Temperature field.

#### **1.17.5.1.15 Field: Minimum Outdoor Temperature**

This is the outdoor temperature (in Celsius) below which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

#### **1.17.5.1.16 Field: Minimum Outdoor Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Minimum Outdoor Temperature field.

#### **1.17.5.1.17 Field: Maximum Outdoor Temperature**

This is the outdoor temperature (in Celsius) above which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

#### 1.17.5.1.18 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Maximum Outdoor Temperature field.

#### 1.17.5.1.19 Field: Maximum Wind Speed

This is the wind speed (m/s) above which ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid chaos in a space (papers blowing around, etc.).

An IDF example is provided below:

```
ZoneVentilation:WindandStackOpenArea,
  ZONE 3 Ventl 1,           !- Name
  ZONE 3,                  !- Zone Name
  0.5,                     !- Opening Area {m2}
  Constant,                !- Opening Area Fraction Schedule Name
  AutoCalculate,           !- Opening Effectiveness
  0.0,                     !- Effective Angle {deg}
  1.0,                     !- Height Difference {m}
  AutoCalculate,           !- Discharge Coefficient for Opening
  18.0,                    !- Minimum Indoor Temperature {C}
  ,                        !- Minimum Indoor Temperature Schedule Name
  ,                        !- Maximum Indoor Temperature {C}
  ,                        !- Maximum Indoor Temperature Schedule Name
  1.0;                    !- Delta Temperature {deltaC}
```

#### 1.17.5.2 Outputs

Current ventilation output variables:

- HVAC,Sum,Zone Ventilation Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Ventilation Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Ventilation Total Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Total Heat Gain Energy [J]
- HVAC,Average,Zone Ventilation Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Zone Ventilation Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Ventilation Current Density Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Ventilation Standard Density Volume [m<sup>3</sup>]

- HVAC,Sum,Zone Ventilation Mass [kg]
- HVAC,Sum,Zone Ventilation Mass Flow Rate [kg/s]
- HVAC,Average,Zone Ventilation Air Change Rate [ach]
- HVAC,Sum,Zone Ventilation Fan Electricity Energy [J]
- HVAC,Average,Zone Ventilation Air Inlet Temperature [C]

Note: If ZoneVentilation:\* objects and ZoneAirBalance:OutdoorAir (with Air Balance Method = Quadrature) objects reference the same Zone Name, the above ventilation output variables will not be reported for that zone. Instead, output variables for zone outdoor air flow will be reported by the corresponding ZoneAirBalance:OutdoorAir object.

#### **1.17.5.2.1 Zone Ventilation Sensible Heat Loss Energy [J]**

The sensible (temperature) heat loss that occurs when the ventilation inlet air temperature < zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.17.5.2.2 Zone Ventilation Sensible Heat Gain Energy [J]**

The sensible (temperature) heat gain that occurs when the ventilation inlet air temperature > = zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.17.5.2.3 Zone Ventilation Latent Heat Loss Energy [J]**

The latent heat loss that occurs when the Ventilation air humidity ratio (outdoor) < zone air humidity ratio from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.17.5.2.4 Zone Ventilation Latent Heat Gain Energy [J]**

The latent heat gain that occurs when the Ventilation air humidity ratio (outdoor) > = zone air humidity ratio from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.17.5.2.5 Zone Ventilation Total Heat Loss Energy [J]**

The total heat loss that occurs when the sum of Zone Ventilation Sensible Heat Gain Energy and Zone Ventilation Latent Heat Gain Energy < the sum of Zone Ventilation Sensible Heat Loss Energy and Zone Ventilation Latent Heat Loss Energy.

#### **1.17.5.2.6 Zone Ventilation Total Heat Gain Energy [J]**

The total heat gain that occurs when the sum of Zone Ventilation Sensible Heat Gain Energy and Zone Ventilation Latent Heat Gain Energy > = the sum of Zone Ventilation Sensible Heat Loss Energy and Zone Ventilation Latent Heat Loss Energy.

#### **1.17.5.2.7 Zone Ventilation Current Density Volume [m<sup>3</sup>]**

#### 1.17.5.2.8 Zone Ventilation Current Density Volume Flow Rate [m<sup>3</sup>/s]

These outputs are the total volume and volume flow rate of ventilation air based on the current density of zone air.

#### 1.17.5.2.9 Zone Ventilation Standard Density Volume [m<sup>3</sup>]

#### 1.17.5.2.10 Zone Ventilation Standard Density Volume Flow Rate [m<sup>3</sup>/s]

These outputs are the total volume and volume flow rate of ventilation air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

#### 1.17.5.2.11 Zone Ventilation Mass [kg]

This output is the total mass flow into a particular zone from outdoors.

#### 1.17.5.2.12 Zone Ventilation Mass Flow Rate [kg/s]

This output is the total mass flow rate into a particular zone from outdoors.

#### 1.17.5.2.13 Zone Ventilation Air Change Rate [ach]

The volume flow rate of the ventilation air in air changes per hour.

#### 1.17.5.2.14 Zone Ventilation Fan Electricity Energy [J]

The fan electrical consumption for Intake or Exhaust ventilation types (for ZoneVentilation:DesignFlowRate objects only).

#### 1.17.5.2.15 Zone Ventilation Air Inlet Temperature [C]

This is equal to the outdoor air temperature except when INTAKE fan power is included (for ZoneVentilation:DesignFlowRate objects only). When intake fan power is used, then the additional heat due to the fan is added to the outdoor temperature and this will be reported as the inlet air temperature. If multiple ventilation objects are specified for a particular zone, the reported value is the mass flow weighted temperature for the multiple ventilation objects specified for this zone.

### 1.17.6 ZoneAirBalance:OutdoorAir

This model calculates a combined zone outdoor airflow by including interactions between mechanical ventilation, infiltration and duct leakage. It is mainly applied to a single zone (e.g., residential) building. The model combines all outdoor airflows from ZoneInfiltration and ZoneVentilation objects in the same zone. This object also includes the induced outdoor airflows due to unbalanced duct leakage, and unbalanced outdoor airflows introduced by unbalanced airflows from [ZoneHVAC:EnergyRecoveryVentilator](#) objects when the exhaust airflow is greater than the supply outdoor airflow. This model is intended for simplified outdoor airflow calculations as opposed to the more detailed outdoor airflow investigations that can be performed with the AirflowNetwork model. The equation used to calculate the combined zone outdoor airflow is:

$$Q = \sqrt{{Q_n}^2 + {Q_{u,v}}^2 + {Q_{u,l}}^2} + Q_{b,v} \quad (1.46)$$

where,

$Q$  = Combined outdoor airflow with infiltration, balanced and unbalanced outdoor air flows, and unbalanced duct leakage [m<sup>3</sup>/s]

$Q_n$  = Natural infiltration airflow from ZoneInfiltration:<sup>\*</sup> objects [m<sup>3</sup>/s]

$Q_{b,v}$  = Balanced ventilation airflow, excluding infiltration [m<sup>3</sup>/s]

$Q_{u,v}$  = Unbalanced ventilation airflow, excluding infiltration [m<sup>3</sup>/s]

$Q_{u,l}$  = Unbalanced duct leakage: the difference between supply and return leaks [m<sup>3</sup>/s]

This object cannot be used simultaneously with the EnergyPlus AirflowNetwork model. If the AirflowNetwork model is active for a simulation time step, the Air Balance Method is reset to “None” for that time step. More advanced outdoor airflow calculations are possible using the EnergyPlus AirflowNetwork model.

This object does not combine any airflows from Fan:ZoneExhaust objects and is independent of HVAC equipment operation.

This object will not work with the AvailabilityManager:HybridVentilation object in the same zone, when the Simple Airflow Control Type Schedule Name is provided in the HybridVentilation object. For this case, the Air Balance Method is reset to “None”.

### 1.17.6.1 Inputs

#### 1.17.6.1.1 Field: Name

The name of the object.

#### 1.17.6.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a combined outdoor airflow statement to a thermal zone in the building.

#### 1.17.6.1.3 Field: Air Balance Method

This choice field determines the air balance method. Two choices are Quadrature and None. If Quadrature, the combined zone outdoor air flow is calculated based on the above equation. If None, no combining of outdoor air will be performed (i.e., any ZoneInfiltration:<sup>\*</sup> and ZoneVentilation:<sup>\*</sup> objects specified for this zone are simulated individually).

#### 1.17.6.1.4 Field: Induced Outdoor Air Due to Unbalanced Duct Leakage

This is the induced outdoor airflow rate, in m<sup>3</sup>/s, due to unbalanced duct leakage. If left blank, the default value is 0.

#### 1.17.6.1.5 Field: Induced Outdoor Air Schedule Name

This field is the name of the schedule (ref: Schedule) which modifies the induced outdoor airflow rate value (see previous field). The schedule values must be any positive number between 0 and 1 as a fraction. The actual induced outdoor airflow rate in a zone for a particular simulation time step is defined as the product of the Induced Outdoor Air Due to Unbalanced Duct Leakage input field and the value specified by the schedule named in this input field.

Note: Since this object is independent of HVAC operation, the inputs for the last two fields should be carefully selected to match HVAC system operation schedules.

An IDF example is provided below:

```
ZoneAirBalance:OutdoorAir,
  ZONE 2 Balance 1,          !- Name
  ZONE 2,                  !- Zone Name
  Quadrature,              !- Air Balance Method
  0.00,                    !- Induced Outdoor Air Due to Unbalanced Duct Leakage {m3/s}
  Constant;                !- Induced Outdoor Air Schedule Name
```

### 1.17.6.2 Outputs

ZoneAirBalance:OutdoorAir output variables will be provided when the Air Balance Method is Quadrature. Output variables from the associated ZoneVentilation:<sup>\*</sup> and ZoneInfiltration:<sup>\*</sup> objects for the same zone will not be produced when ZoneAirBalance:OutdoorAir output variables are available. If the Air Balance Method = None, then no ZoneAirBalance:OutputAir outputs will be produced and the associated ZoneVentilation:<sup>\*</sup> and ZoneInfiltration:<sup>\*</sup> objects will specify their output variables for the zone.

- HVAC,Sum,Zone Combined Outdoor Air Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Total Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Total Heat Gain Energy [J]
- HVAC,Average,Zone Combined Outdoor Air Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Zone Combined Outdoor Air Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Combined Outdoor Air Current Density Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Combined Outdoor Air Standard Density Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Combined Outdoor Air Mass [kg]
- HVAC,Sum,Zone Combined Outdoor Air Mass Flow Rate [kg/s]
- HVAC,Average, Zone Combined Outdoor Air Changes per Hour [ach]
- HVAC,Sum, Zone Combined Outdoor Air Fan Electricity Energy [J]

#### 1.17.6.2.1 Zone Combined Outdoor Air Sensible Heat Loss Energy [J]

The sensible (temperature) heat loss that occurs when the outdoor air temperature < zone air temperature.

#### 1.17.6.2.2 Zone Combined Outdoor Air Sensible Heat Gain Energy [J]

The sensible (temperature) heat gain that occurs when the outdoor air temperature > = zone air temperature.

#### 1.17.6.2.3 Zone Combined Outdoor Air Latent Heat Loss Energy [J]

The latent heat loss that occurs when the outdoor air humidity ratio < zone air humidity ratio.

#### 1.17.6.2.4 Zone Combined Outdoor Air Latent Heat Gain Energy [J]

The latent heat gain that occurs when the outdoor air humidity ratio > = zone air humidity ratio.

#### 1.17.6.2.5 Zone Combined Outdoor Air Total Heat Loss Energy [J]

The total heat loss that occurs when the sum of Zone Combined Outdoor Air Sensible Heat Gain Energy and Zone Combined Outdoor Air Latent Heat Gain Energy < the sum of Zone Combined Outdoor Air Sensible Heat Loss Energy and Zone Combined Outdoor Air Latent Heat Loss Energy.

### 1.17.6.2.6 Zone Combined Outdoor Air Total Heat Gain Energy [J]

The total heat gain that occurs when the sum of Zone Combined Outdoor Air Sensible Heat Gain Energy and Zone Combined Outdoor Air Latent Heat Gain Energy > = the sum of Zone Combined Outdoor Air Sensible Heat Loss Energy and Zone Combined Outdoor Air Latent Heat Loss Energy.

### 1.17.6.2.7 Zone Combined Outdoor Air Current Density Volume [m<sup>3</sup>]

### 1.17.6.2.8 Zone Combined Outdoor Air Current Density Volume Flow Rate [m<sup>3</sup>/s]

These outputs are the total volume and volume flow rate of outdoor air based on the current density of zone air.

### 1.17.6.2.9 Zone Combined Outdoor Air Standard Density Volume [m<sup>3</sup>]

### 1.17.6.2.10 Zone Combined Outdoor Air Standard Density Volume Flow Rate [m<sup>3</sup>/s]

These outputs are the total volume and volume flow rate of outdoor air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

### 1.17.6.2.11 Zone Combined Outdoor Air Mass [kg]

This output is the total mass flow into a particular zone from outdoors.

### 1.17.6.2.12 Zone Combined Outdoor Air Mass Flow Rate [kg/s]

This output is the total mass flow rate into a particular zone from outdoors.

### 1.17.6.2.13 Zone Combined Outdoor Air Changes per Hour [ach]

The volume flow rate of the ventilation air in air changes per hour.

### 1.17.6.2.14 Zone Combined Outdoor Air Fan Electricity Energy [J]

The fan electrical consumption for Intake, Exhaust, or Balanced ventilation types (for ZoneVentilation:DesignFlowRate objects used to calculate a combined zone outdoor airflow).

## 1.17.7 ZoneMixing

ZoneMixing is intended to allow simplified treatment of air exchange between zones. Note that this statement only affects the energy balance of the “receiving” zone and that this statement will not produce any effect on the “source” zone. ZoneMixing statements can be complementary and include multiple zones, but the balancing of flows between zones is left to the user’s discretion. Also see [ZoneCrossMixing](#) and [ZoneRefrigerationDoorMixing](#). More advanced mixing calculations are possible using the EnergyPlus AirflowNetwork model for multi-zone airflow with or without HVAC system operation.

### 1.17.7.1 Inputs

#### 1.17.7.1.1 Field: Name

The name of the ZoneMixing object.

### 1.17.7.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular mixing statement to a thermal zone in the building.

### 1.17.7.1.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

### 1.17.7.1.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

### 1.17.7.1.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $\text{m}^3/\text{s}$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

### 1.17.7.1.6 Field: Flow Rate per Zone Floor Area

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

### 1.17.7.1.7 Field: Flow Rate per Person

This factor ( $\text{m}^3/\text{s}\cdot\text{person}$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

#### 1.17.7.1.8 Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### 1.17.7.1.9 Field: Source Zone Name

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field.

#### 1.17.7.1.10 Field: Delta Temperature

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which the air is being drawn (source zone) must be “Delta Temperature” warmer than the receiving zone air or else no mixing occurs. If this field is negative, the temperature of the source zone must be “Delta Temperature” cooler than the receiving zone air or else no mixing occurs. If this parameter is zero, mixing occurs regardless of the relative zone temperatures.

#### 1.17.7.1.11 Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

#### 1.17.7.1.12 Field: Minimum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum receiving zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

#### 1.17.7.1.13 Field: Maximum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum receiving zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

**Note:** The maximum zone temperature when mixing is shutoff must be greater than or equal to the minimum zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

#### 1.17.7.1.14 Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum source zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

#### 1.17.7.1.15 Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum source zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum

temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

**Note:** The maximum source zone temperature when mixing is shutoff must be greater than or equal to the minimum source zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

#### 1.17.7.1.16 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

#### 1.17.7.1.17 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum outdoor temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

**Note:** The maximum outdoor temperature when mixing is shutoff must be greater than or equal to the minimum outdoor temperature which mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

An IDF Example:

```

```

#### 1.17.7.2 Outputs

- HVAC,Sum,Zone Mixing Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Mass [kg]
- HVAC,Sum,Zone Mixing Mass Flow Rate [kg/s]
- HVAC,Sum,Zone Mixing Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Gain Energy [J]

- HVAC,Sum,Zone Mixing Total Heat Loss [J]
- HVAC,Sum,Zone Mixing Total Heat Gain Energy [J]

#### **1.17.7.2.1 Zone Mixing Volume [m<sup>3</sup>]**

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.17.7.2.2 Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

#### **1.17.7.2.3 Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

#### **1.17.7.2.4 Zone Mixing Mass [kg]**

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

#### **1.17.7.2.5 Zone Mixing Mass Flow Rate [kg/s]**

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.17.7.2.6 Zone Mixing Sensible Heat Loss Energy [J]**

#### **1.17.7.2.7 Zone Mixing Sensible Heat Gain Energy [J]**

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

#### **1.17.7.2.8 Zone Mixing Latent Heat Loss Energy [J]**

#### **1.17.7.2.9 Zone Mixing Latent Heat Gain Energy [J]**

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

### 1.17.7.2.10 Zone Mixing Total Heat Loss Energy [J]

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

### 1.17.7.2.11 Zone Mixing Total Heat Gain Energy [J]

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy > = the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

## 1.17.8 ZoneCrossMixing

ZoneCrossMixing is ideally suited for two zones that exchange an equal amount of air between each other. As with [ZoneMixing](#), this is a simplified interzone airflow in EnergyPlus. The main difference between [ZoneMixing](#) and ZoneCrossMixing is that cross mixing has an energy effect on both the source and the receiving zone, thus maintaining both the air mass and energy balances in the two zones. For refrigerated zones, see [ZoneRefrigerationDoorMixing](#). More advanced mixing calculations are possible using the EnergyPlus AirflowNetwork model for multi-zone airflow with or without HVAC system operation.

ZoneCrossMixing can be entered once (in one of the mixing zones), twice (once for each zone), or multiple times (exchanging with more than one zone). Each object will be modeled with its own control conditions. The object may be entered once if Delta Temperature > 0.0 and it is desirable to have mixing only when the source zone is warmer than the receiving zone. This might be the case when the warmer zone is below the colder zone and the mixing is buoyancy driven. If the zones are next to each other, separated by an open doorway, it would be more suitable to input a cross mixing object for each zone. Then mixing would occur if the zone temperatures differed by Delta Temperature or greater regardless of which is the warmer zone.

### 1.17.8.1 Inputs

#### 1.17.8.1.1 Field: Name

The name of the ZoneCrossMixing object.

#### 1.17.8.1.2 Field: Zone Name

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular cross mixing statement to a thermal zone in the building.

#### 1.17.8.1.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

#### 1.17.8.1.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The flow per person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### 1.17.8.1.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $\text{m}^3/\text{s}$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

#### 1.17.8.1.6 Field: Flow Rate per Zone Floor Area

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

#### 1.17.8.1.7 Field: Flow Rate per Person

This factor ( $\text{m}^3/\text{s}\cdot\text{person}$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

#### 1.17.8.1.8 Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### 1.17.8.1.9 Field: Source Zone Name

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field. In reality, the “source” and “receiving” zones are interchangeable since the cross-mixed air affects both zones.

#### 1.17.8.1.10 Field: Delta Temperature

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which air is being drawn (“source zone”) must be “Delta Temperature” warmer than the zone air or no mixing occurs. If this field is zero, mixing occurs regardless of the relative air temperatures. Negative values for “Delta Temperature” are not permitted.

#### 1.17.8.1.11 Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

#### 1.17.8.1.12 Field: Minimum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum receiving zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

#### 1.17.8.1.13 Field: Maximum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum receiving zone temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

**Note:** The maximum zone temperature when cross mixing is shutoff must be greater than or equal to the minimum zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

#### 1.17.8.1.14 Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum source zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

#### 1.17.8.1.15 Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum source zone temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

**Note:** The maximum source zone temperature when cross mixing is shutoff must be greater than or equal to the minimum source zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

#### 1.17.8.1.16 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

### 1.17.8.1.17 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum outdoor temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

**Note:** The maximum outdoor temperature when cross mixing is shutoff must be greater than or equal to the minimum outdoor temperature which cross mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

An IDF Example:

### 1.17.8.2 Outputs

- HVAC,Sum,Zone Mixing Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Mass [kg]
- HVAC,Sum,Zone Mixing Mass Flow Rate [kg/s]
- HVAC,Sum,Zone Mixing Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Gain Energy [J]

### 1.17.8.2.1 Zone Mixing Volume [m<sup>3</sup>]

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

### 1.17.8.2.2 Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

### 1.17.8.2.3 Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

### 1.17.8.2.4 Zone Mixing Mass [kg]

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

### 1.17.8.2.5 Zone Mixing Mass Flow Rate [kg/s]

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

### 1.17.8.2.6 Zone Mixing Sensible Heat Loss Energy [J]

### 1.17.8.2.7 Zone Mixing Sensible Heat Gain Energy [J]

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

### 1.17.8.2.8 Zone Mixing Latent Heat Loss Energy [J]

### 1.17.8.2.9 Zone Mixing Latent Heat Gain Energy [J]

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

### 1.17.8.2.10 Zone Mixing Total Heat Loss Energy [J]

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

### 1.17.8.2.11 Zone Mixing Total Heat Gain Energy [J]

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy > = the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

## 1.17.9 ZoneRefrigerationDoorMixing

`ZoneRefrigerationDoorMixing` is ideally suited for two zones, at least one of which is refrigerated, that exchange an equal amount of dry air. As with `ZoneMixing`, this is a simplified interzone airflow in EnergyPlus. The `ZoneRefrigerationDoorMixing` approach shares some features of both `ZoneMixing` and `ZoneCrossMixing`. Like `ZoneCrossMixing`, `ZoneRefrigerationDoorMixing` has an energy effect on both the source and the receiving zone, thus maintaining both the air mass and energy balances in the two zones. Unlike the other two mixing objects, `ZoneRefrigerationDoorMixing` always calculates the air exchange rate based on the zone temperature and relative humidity. That is, the user does not specify the air flow rate. The user can moderate the flow through a door-opening schedule.

`ZoneRefrigerationDoorMixing` can only be entered once for any unique pair of zones. It doesn't matter which zone is listed first and the zones will automatically switch back and forth between source and receiving zones depending upon which zone is colder.

### 1.17.9.1 Inputs

#### 1.17.9.1.1 Field: Name

The name of the `ZoneRefrigerationDoorMixing` object.

#### 1.17.9.1.2 Field: Zone 1 Name

This field is the name of one of the two zones (ref: `Zone`) exchanging air and attaches a particular refrigeration door mixing statement to both thermal zones in the building.

#### 1.17.9.1.3 Field: Zone 2 Name

This field is the name of the other zone (ref: `Zone`) exchanging air and attaches a particular refrigeration door mixing statement to both thermal zones in the building.

#### 1.17.9.1.4 Field: Schedule Name

This field is the name of the schedule (ref: `Schedule`) that modifies the door opening between the two zones and should contain values between 0.0 and 1.0.

#### 1.17.9.1.5 Field: Door Height

This field denotes the door opening height (m). The default value is 3 m.

#### 1.17.9.1.6 Field: Door Area

This field denotes the door opening area ( $m^2$ ). The default value is 9  $m^2$ .

### 1.17.9.1.7 Field: Door Protection Type

This field is a key/choice field that tells how the door is protected. The impact of this choice is described in the Engineering Reference. The key/choices are:

- None

None, or no door protection is the default choice

- AirCurtain
- StripCurtain

An IDF Example:

```
ZoneRefrigerationDoorMixing,
  Freezer1_Cooler1,    !- Name
  Freezer1,           !- Zone 1 Name
  Cooler1,            !- Zone 2 Name
  Freezer1DoorSched, !- Schedule Name
  1.8,                !- Door height {m}
  2.3,                !- Door area {m2}
  StripCurtain;       !- Door protection type
```

## 1.17.9.2 Outputs

- HVAC,Sum,Zone Mixing Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Zone Mixing Mass [kg]
- HVAC,Sum,Zone Mixing Mass Flow Rate [kg/s]
- HVAC,Sum,Zone Mixing Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Gain Energy [J]

### 1.17.9.2.1 Zone Mixing Volume [m<sup>3</sup>]

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

### 1.17.9.2.2 Zone Mixing Current Density Volume Flow Rate [m<sup>3</sup>/s]

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

### **1.17.9.2.3 Zone Mixing Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

### **1.17.9.2.4 Zone Mixing Mass [kg]**

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

### **1.17.9.2.5 Zone Mixing Mass Flow Rate [kg/s]**

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

### **1.17.9.2.6 Zone Mixing Sensible Heat Loss Energy [J]**

### **1.17.9.2.7 Zone Mixing Sensible Heat Gain Energy [J]**

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

### **1.17.9.2.8 Zone Mixing Latent Heat Loss Energy [J]**

### **1.17.9.2.9 Zone Mixing Latent Heat Gain Energy [J]**

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

### **1.17.9.2.10 Zone Mixing Total Heat Loss Energy [J]**

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

### **1.17.9.2.11 Zone Mixing Total Heat Gain Energy [J]**

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy >= the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

## 1.17.10 ZoneEarthTube

An earth tube is a long, underground metal or plastic pipe through which air is drawn. During cooling season, as air travels through the pipe, it gives up some of its heat to the surrounding soil and enters the room as cooler air. Similarly, during heating season, as air travels through the pipe, it receives some of its heat from the soil and enters the room as warmer air. Simple earth tubes in EnergyPlus can be controlled by a schedule and through the specification of minimum, maximum, and delta temperatures as described below. As with infiltration and ventilation, the actual flow rate of air through the earth tube can be modified by the temperature difference between the inside and outside environment and the wind speed. The basic equation used to calculate air flow rate of earth tube in EnergyPlus is:

$$\text{EarthTubeFlowRate} = (E_{\text{design}}) (F_{\text{schedule}}) [A + B |T_{\text{zone}} - T_{\text{odb}}| + C (\text{WindSpeed}) + D (\text{WindSpeed}^2)] \quad (1.47)$$

For the simulation of the earth tube, a weather data file is required and, therefore, the earth tube cannot run without weather data file. The required input fields to simulate the earth tube include the average soil surface temperature, the amplitude of soil surface temperature, and the phase constant of soil surface temperature. These fields should be calculated in advance by using a separate stand-alone program (CalcSoilSurfTemp) and should be input into earth tube.

### 1.17.10.1 CalcSoilSurfTemp – Auxiliary Programs Document

The CalcSoilSurfTemp program is simple and requires only two input fields : soil condition and soil surface condition in addition to a valid weather file. For soil condition, the user should select the number corresponding to the actual condition of the soil surrounding the earth tube from the four following options: 1. HEAVY AND SATURATED, 2. HEAVY AND DAMP, 3. HEAVY AND DRY and 4. LIGHT AND DRY. This determines the thermal diffusivity and thermal conductivity of the surrounding soil. For soil surface conditions, the user should select the number corresponding to the actual condition of the ground surface above the earth tube from the eight following options: 1. BARE AND WET, 2. BARE AND MOIST, 3. BARE AND ARID, 4. BARE AND DRY, 5. COVERED AND WET, 6. COVERED AND MOIST, 7. COVERED AND ARID and 8. COVERED AND DRY. This determines the absorption coefficient and the fraction of evaporation rate of the ground surface.

From this information and an analysis of the weather for the location selected, the CalcSoilSurfTemp program (ref. Auxiliary Programs document) calculates the three parameters listed above. The user must then add these parameters as input into EnergyPlus. The full input description of an earth tube in EnergyPlus is given below.

### 1.17.10.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular earth tube statement to a thermal zone in the building.

### 1.17.10.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 is noted as  $F_{\text{schedule}}$  in the above equation.

### 1.17.10.4 Field: Design Flow Rate

This number (noted as  $E_{\text{design}}$  in the above equation) is the maximum amount of air mass flow rate of the earth tube expected at design conditions. The flow rate is expressed in units of  $\text{m}^3/\text{s}$ . The design value is

modified by the schedule fraction (see previous field) and user specified coefficients (see last four fields).

#### 1.17.10.5 Field: Minimum Zone Temperature when Cooling

This is the indoor temperature (in Celsius) below which the earth tube is shut off. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then earth tube is automatically turned off.

#### 1.17.10.6 Field: Maximum Zone Temperature when Heating

This is the indoor temperature (in Celsius) above which the earth tube is shut off. This higher temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is below 20°C. If the zone air temperature rises above 20°C, then earth tube is automatically turned off.

#### 1.17.10.7 Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which the earth tube is shut off. This is to allow the earth tube to be stopped either if the temperature outside is too warm and could potentially heat the space or if the temperature outside is too cold and could potentially cool the space. For example, if the user specifies a delta temperature of 2°C, earth tube is assumed to be available if the temperature difference between indoor and outdoor temperature is at least 2°C. If the outside air dry-bulb temperature is less than 2°C cooler or warmer than the indoor dry-bulb temperature, then the earth tube is automatically turned off.

#### 1.17.10.8 Field: Earthtube Type

This alpha character string defines the type of earth tube as one of the following options: Natural, Exhaust, or Intake. A natural earth tube is assumed to be air movement/exchange that will not consume any fan energy or is the result of natural air flow through the tube and into the building. Values for fan pressure and efficiency for a natural flow earth tube are ignored. For either EXHAUST or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaustearth tubes, the conditions of the air entering the space are assumed to be equivalent to the air which is cooled or heated by passing along the pipe. For Intake earth tubes, an appropriate amount of fan heat is added to the air stream.

#### 1.17.10.9 Field: Fan Pressure Rise

This is the pressure rise experienced across the fan in Pascals ( $N/m^2$ ). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

#### 1.17.10.10 Field: Fan Total Efficiency

This is the total fan efficiency (a decimal number between 0.0 and 1.0). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

### **1.17.10.11 Field: Pipe Radius**

This is the radius of the earth tube/pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. If the pipe has non-circular cross section, user can use the concept of hydraulic diameter as follows.

$$D = 4 \times \text{Area} / \text{Perimeter} \quad (1.48)$$

However, since this field requires the pipe radius, hydraulic diameter should be divided by two.

### **1.17.10.12 Field: Pipe Thickness**

This is the thickness of the pipe wall (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

### **1.17.10.13 Field: Pipe Length**

This is the total length of the pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. As the length of the pipe becomes longer, the amount of the heat transfer becomes larger.

### **1.17.10.14 Field: Pipe Thermal Conductivity**

This is the thermal conductivity of the pipe (in W/m°C). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

### **1.17.10.15 Field: Pipe Depth Under Ground Surface**

This is the depth of the pipe under the ground surface (in meters). This plays a role in determining the temperature of the soil surrounding the pipe.

### **1.17.10.16 Field: Soil Condition**

This alpha character string defines the actual condition of the soil surrounding the earth tube and can be one of any of the following options: HeavyAndSaturated, HeavyAndDamp, HeavyAndDry or LightAndDry. This determines the thermal diffusivity and thermal conductivity of the surrounding soil, which play a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

### **1.17.10.17 Field: Average Soil Surface Temperature**

This is the annual average soil surface temperature straight above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

### **1.17.10.18 Field: Amplitude of Soil Surface Temperature**

This is the amplitude of soil surface temperature above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This is the difference between the maximum and minimum soil surface temperature for the whole year divided by two. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

### 1.17.10.19 Field: Phase Constant of Soil Surface Temperature

This is the phase constant of the soil surface temperature straight above the earth tube, which play a role in determining the temperature of the soil surrounding the pipe at particular time. This is the time elapsed from the beginning of the year until the soil surface temperature reaches the minimum value of the year. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

### 1.17.10.20 Field: Constant Term Flow Coefficient

This number is the “A” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

### 1.17.10.21 Field: Temperature Term Flow Coefficient

This number is the “B” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

### 1.17.10.22 Field: Velocity Term Flow Coefficient

This number is the “C” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

### 1.17.10.23 Field: Velocity Squared Term Flow Coefficient

This number is the “D” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are  $s^2/m^2$ .

### 1.17.11 ZoneEarthTube Outputs

Current Earth Tube output variables:

- HVAC,Sum,Earth Tube Zone Sensible Cooling Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Cooling Rate [W]
- HVAC,Sum,Earth Tube Zone Sensible Heating Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Heating Rate [W]
- HVAC,Sum,Earth Tube Air Flow Volume [m<sup>3</sup>]
- HVAC,Average,Earth Tube Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Earth Tube Standard Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Sum,Earth Tube Air Flow Mass [kg]
- HVAC,Average,Earth Tube Air Mass Flow Rate [kg/s]
- HVAC,Average,Earth Tube Water Mass Flow Rate [kg/s]
- HVAC,Sum,Earth Tube Fan Electricity Energy [J]
- HVAC,Average,Earth Tube Fan Electricity Rate [W]
- HVAC,Average,Earth Tube Zone Inlet Air Temperature [C]
- HVAC,Average,Earth Tube Ground Interface Temperature [C]
- HVAC,Average,Earth Tube Outdoor Air Heat Transfer Rate [W]
- HVAC,Average,Earth Tube Inlet Wet Bulb Temperature [C]
- HVAC,Average,Earth Tube Inlet Humidity Ratio [kgWater/kgDryAir]

#### 1.17.11.1 Earth Tube Zone Sensible Cooling Energy [J]

#### 1.17.11.2 Earth Tube Zone Sensible Cooling Rate [W]

These are the energy and rate associated with the zone cooling provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is less than zone air temperature.

#### 1.17.11.3 Earth Tube Zone Sensible Heating Energy [J]

#### 1.17.11.4 Earth Tube Zone Sensible Heating Rate [W]

These are the energy and rate associated with the zone heating provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is greater than the zone air temperature.

#### 1.17.11.5 Earth Tube Air Flow Volume [m<sup>3</sup>]

The volume flow of air through the earth tube.

**1.17.11.6 Earth Tube Current Density Volume Flow Rate [m<sup>3</sup>/s]**

The volume flow rate of air through the earth tube evaluating density at current zone conditions.

**1.17.11.7 Earth Tube Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

The volume flow rate of air through the earth tube evaluating density at standard conditions.

**1.17.11.8 Earth Tube Air Flow Mass [kg]**

The mass flow of air through the earth tube.

**1.17.11.9 Earth Tube Air Mass Flow Rate [kg/s]**

The mass flow rate of air through the earth tube.

**1.17.11.10 Earth Tube Water Mass Flow Rate [kg/s]**

The mass flow rate of water vapor at the exit of the earth tube.

**1.17.11.11 Earth Tube Fan Electricity Energy [J]****1.17.11.12 Earth Tube Fan Electricity Rate [W]**

These are the fan electricity consumption and power for intake or exhaust earth tube types.

**1.17.11.13 Earth Tube Zone Inlet Air Temperature [C]**

This is the temperature of the air entering the zone after passing through the earth tube [C]. This temperature includes the cooling or heating of outdoor air as it passes along the pipe. When intake fan assist is used, then the additional heat due to the fan is included in the inlet air temperature.

**1.17.11.14 Earth Tube Ground Interface Temperature [C]**

This is the average temperature of the ground along the outer surface of the earth tube [C].

**1.17.11.15 Earth Tube Outdoor Air Heat Transfer Rate [W]**

This is the rate of heat transfer from the earth tube to the outdoor air [W]. Positive values indicate the rate at which outdoor air is preheated; negative values indicate the rate of precooling.

**1.17.11.16 Earth Tube Zone Inlet Wet Bulb Temperature [C]**

This is the wet bulb temperature of the air entering the zone after passing through the earth tube [C].

**1.17.11.17 Earth Tube Zone Inlet Humidity Ratio [kgWater/kgDryAir]**

This is the humidity ratio of the air entering the zone after passing through the earth tube [kgWater/kgDryAir].

## 1.17.12 ZoneCoolTower:Shower

A cooltower (which is sometimes referred to as a wind tower or a shower cooling tower) is a component that is intended to model a passive downdraught evaporative cooling (PDEC) that is designed to capture the wind at the top of a tower and cool the outside air using water evaporation before delivering it to a space. The air flow in these systems is natural as the evaporation process increases the density of the air causing it to fall through the tower and into the space without the aid of a fan. A cooltower typically consists of a water spray or an evaporative pad, a shaft, and a water tank or reservoir. Wind catchers to improve the wind-driven performance at the top of the tower are optional. Water is pumped over an evaporative device by water pump which is the only component consumed power for this system. This water cools and humidifies incoming air and then the cool, dense air naturally falls down through shaft and leaves through large openings at the bottom of cooltowers.

The shower cooling tower can be controlled by a schedule and the specification of maximum water flow rate and volume flow rate as well as minimum indoor temperature. The actual flow rate of water and air can be controlled as users specify the fractions of water loss and flow schedule. The required input fields include effective tower height and exit area to obtain the temperature and flow rate of the air exiting the tower. A schedule and rated power for the water pump are also required to determine the power consumed. The component typically has a stand alone water system that is not added to the water consumption from mains. However, users are required to specify the water source through an optional field, the name of water supply storage tank, in case any water comes from a water main. The model is described more fully in the Engineering Reference document.

This model requires weather information obtained from either design day or weather file specifications. The control is accomplished by either specifying the water flow rate or obtaining the velocity at the outlet with inputs and weather conditions when the water flow rate is unknown. As with infiltration, ventilation, and earth tubes, the component is treated in a similar fashion to “natural ventilation” in EnergyPlus.

### 1.17.12.1 Inputs

#### 1.17.12.1.1 Field: Name

This field is a unique user assigned name for each cooltower. Any reference to this unit by another object will use this name.

#### 1.17.12.1.2 Field: Availability Schedule Name

This field is the name of the schedule that denotes whether the cooltower can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the cooltower is available and can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the cooltower is not available and must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.17.12.1.3 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular cooltower statement to a thermal zone in the building.

#### 1.17.12.1.4 Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooltower obtains water used for evaporative cooling. If blank or omitted, then the cooltower will obtain water directly from local water main. If the name of a Water Storage Tank object is used here, then the cooltower will obtain its water from that tank. If a tank is specified, the cooltower will attempt to obtain all the water it uses from the tank. However, if

the tank cannot provide all the water the cooltower needs, then the cooltower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

#### 1.17.12.1.5 Field: Flow Control Type

This field specifies how the user wishes to control the cooltower. The air flow from the cooltower may be controlled by either the water flow rate along with the water pump schedule or naturally driven by wind flow. The user must select from the following options: **WaterFlowSchedule** and **WindDrivenFlow**. If the user either wishes to control the water flow rate or has information about the water flow rate, **WaterFlowSchedule** must be selected. **WindDrivenFlow** for cooltower flow control must be selected when the water flow rate is unknown and the user wishes to have the flow rate of both air and water controlled by the external weather conditions (wind speed). If the user does not select a control type, **WindDrivenFlow** is assumed as a flow control type.

#### 1.17.12.1.6 Field: Pump Flow Rate Schedule Name

This field modifies the maximum flow rate of water through the cooltower in m<sup>3</sup>/sec. This input is “optional.” If the user does not enter a schedule, the flow rate through the cooltower is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one.

#### 1.17.12.1.7 Field: Maximum Water Flow Rate

This field is the maximum water flow rate distributed to the tower in m<sup>3</sup>/s. This limit is intended to avoid over estimation of water flow rate, which leads higher air flow rate and exit temperature of the air.

#### 1.17.12.1.8 Field: Effective Tower Height

This field is the effective tower height for evaporative cooling, from the water spray to the top of the exit in m.

#### 1.17.12.1.9 Field: Airflow Outlet Area

This field is the area at the exit of the tower in m<sup>2</sup>. This field is used to determine the air flow rate leaving the tower with the velocity of the air flow.

#### 1.17.12.1.10 Field: Maximum Air Flow Rate

This field is the maximum volumetric flow rate of the air leaving the tower in m<sup>3</sup>/s. This airflow maximum allows the cooltower performance to be limited if the outside wind speed and the tower height are relatively high and thus result in high airflow supplied to the space.

#### 1.17.12.1.11 Field: Minimum Indoor Temperature

This field is the minimum indoor temperature in Celsius below which cooltower is shutoff. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, cooltower is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then cooltower is automatically turned off.

#### 1.17.12.1.12 Field: Fraction of Water Loss

This field specifies the fraction of the loss of water during either operation or transient operation. If the user does not enter a fraction, no loss of water is assumed and the cooltower water consumption includes only evaporation. Note that the fraction must be between zero and one.

### 1.17.12.1.13 Field: Fraction of Flow Schedule

This field specifies the fraction of the airflow that actually goes to the outside. The user who wishes to control the actual flow to the inside of the building must specify the value of the fraction. If the user does not enter a fraction, the calculated flow rate is the “zone cooltower volume flow rate.” Note that the fraction must be between zero and one.

### 1.17.12.1.14 Field: Rated Power Consumption

This field is the pump’s rated power consumption in Watts.

Below is an example input for a cooltower.

```
ZoneCoolTower:Shower
  Cool Tower 1,           !- Name of cooltowers
  Zone 1,                !- Zone name

- HVAC,Sum,Zone Cooltower Mains Water Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Cooltower Storage Tank Water Volume [m<sup>3</sup>]
- HVAC,Sum,Zone Cooltower Starved Mains Water Volume [m<sup>3</sup>]

#### **1.17.12.2.1 Zone Cooltower Sensible Heat Loss Energy [J]**

#### **1.17.12.2.2 Zone Cooltower Sensible Heat Loss Rate [W]**

The sensible heat loss that occurs when the temperature at the exit of the cooltower is less than that of the zone.

#### **1.17.12.2.3 Zone Cooltower Latent Heat Loss Energy [J]**

#### **1.17.12.2.4 Zone Cooltower Latent Heat Loss Rate [W]**

The latent heat loss that occurs when the humidity ratio at the exit of the cooltower is greater than that of the zone.

#### **1.17.12.2.5 Zone Cooltower Current Density Air Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of the air leaving the cooltower evaluating density at current zone conditions.

#### **1.17.12.2.6 Zone Cooltower Standard Density Air Volume Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of the air leaving the cooltower evaluating density at standard conditions.

#### **1.17.12.2.7 Zone Cooltower Air Volume [m<sup>3</sup>]**

The sum of actual volumetric flow of the air leaving cooltower

#### **1.17.12.2.8 Zone Cooltower Air Mass Flow Rate [kg/s]**

The mass flow rate of the air leaving the cooltower

#### **1.17.12.2.9 Zone Cooltower Air Mass [kg]**

The sum of actual mass flow of the air leaving the cooltower

#### **1.17.12.2.10 Zone Cooltower Air Inlet Temperature [C]**

The dry-bulb temperature of the outdoor air at the inlet of the cooltower

#### **1.17.12.2.11 Zone Cooltower Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the outdoor air at the inlet of the cooltower

#### **1.17.12.2.12 Zone Cooltower Air Outlet Temperature [C]**

The temperature at the exit of the cooltower.

#### **1.17.12.2.13 Zone Cooltower Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the air at the exit of the cooltower.

#### **1.17.12.2.14 Zone Cooltower Water Volume [m<sup>3</sup>]**

The water consumption includes not only the direct thermodynamics of water evaporation but also other sources of consumption such as drift or concentration blow down specified by users throughout all processes during the operation.

#### **1.17.12.2.15 Zone Cooltower Mains Water Volume [m<sup>3</sup>]**

This is the water consumed by the cooltower that actually be met by the mains water. This output variable appears only when the water comes from mains.

#### **1.17.12.2.16 Zone Cooltower Storage Tank Water Volume [m<sup>3</sup>]**

This is the water consumed by the cooltower that actually be met by the water storage tank. If any amount of the water is starved from mains, this water consumption is the difference between the Zone Cooltower Water Volume and the following output. This output variable appears only when the water comes from storage tank waters.

#### **1.17.12.2.17 Zone Cooltower Starved Mains Water Volume [m<sup>3</sup>]**

This is the source (mains) of water consumed by the cooltower that could not actually be met by the storage tank. This output variable appears only when the water comes from storage tank waters.

#### **1.17.12.2.18 Zone Cooltower Pump Electricity Rate [W]**

The power consumed by the recirculating pump in Watts.

#### **1.17.12.2.19 Zone Cooltower Pump Electricity Energy [J]**

The energy consumed by the recirculating pump in Joules.

### **1.17.13 ZoneThermalChimney**

A thermal chimney is a vertical shaft utilizing solar radiation to enhance the natural ventilation in buildings. It consists of a absorber wall, air gap and glass cover with high solar transmissivity. For the high solar absorption, it is usually south facing.

The key output parameter in the thermal chimney model is the enhanced amount of natural ventilation rate caused by the presence of a thermal chimney. In order to determine the enhanced ventilation, the discharge air temperature from a thermal chimney should be calculated, which, in turn, should be computed based on the information on the absorber wall temperature, glass cover temperature and the vertical air temperature distribution within the thermal chimney. Among them, energy balances for the absorber wall and the glass cover are carried out using the existing algorithm currently available in EnergyPlus, which has the similar approach to the Trombe wall. As stated in the Trombe wall object as well, this approach allows the flexibility for users to specify the various wall parameters and to explore unusual configurations. On the other hand, the vertical air temperature distribution and the resultant discharge air temperature of the thermal chimney are computed using the separate thermal chimney algorithm described in the Engineering Reference document.

Similar to the Trombe wall model, a zone is coupled to the desired surface via an interzone partition. To simulate the thermal chimney, the Solar Distribution field in the Building object should be set to FullInteriorAndExterior so that the majority of the solar flux is directed on the absorber wall. For a normal sized thermal chimney zone, the user can set the Zone Inside Convection Algorithm to “Detailed”, which takes into account natural convection effects intended for a normal zone. For a narrow cavity zone having high aspect ratios, there is no built-in algorithm for calculating the correct convection coefficients on the inside of thermal chimney zone walls. One option is to use the “Detailed” convection algorithm

similar to the Trombe wall model. However, some error may be incurred when used with a narrow zone. Another option is to use the **SurfaceProperty:ConvectionCoefficients** object to schedule coefficients that have been determined beforehand by the user. In addition, the wall construction of the adjoining zone must be the mirror image of the wall construction in the thermal chimney zone.

The full input description of a thermal chimney in EnergyPlus is given below.

#### 1.17.13.1 Field: Name

This field is a unique user assigned name for an instance of the thermal chimney system.

#### 1.17.13.2 Field: Zone Name

This field is the name of the thermal chimney zone (ref: Zone). Since the thermal chimney is not only a system component but also a zone itself, this field is also necessary. It should be differentiated from the *Zone name* field described later.

#### 1.17.13.3 Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the thermal chimney can operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the system is available and can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the system is not available and must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.17.13.4 Field: Width of the Absorber Wall

This number is the width of the absorber wall in the thermal chimney. The width is expressed in units of m. Even though this value is specified in Surface objects as well, this value is used to compute the discharge air temperature and the enhanced ventilation rate caused by the thermal chimney.

#### 1.17.13.5 Field: Cross Sectional Area of Air Channel Outlet

This number is the cross sectional area of air channel outlet. The area is expressed in units of m<sup>2</sup>. The enhanced air flow rate by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet. Cross sectional areas of air channel inlet will be described later in conjunction with the distance from the top of thermal chimney to each inlet and relative ratios of air flow rates passing through each inlet.

#### 1.17.13.6 Field: Discharge Coefficient

This dimensionless number is the discharge coefficient of the thermal chimney. The ventilation rate enhanced by the thermal chimney is also dependent on the discharge coefficient.

#### 1.17.13.7 Field: Zone <#> Name

This field is the name of the zone (ref: Zone) to which the thermal chimney is attached. It is used in conjunction with the next three fields. Note that up to 20 sets of zone name, distance from the top of the thermal chimney to each inlet, relative ratios of air flow rates passing through each zone and cross sectional areas of each air channel inlet may be entered for a single thermal chimney if multiple zones share the common thermal chimney.

### 1.17.13.8 Field: Distance from Top of Thermal Chimney to Inlet <#>

This field is the distance from the top of the thermal chimney to each inlet corresponding to each zone. It is used in conjunction with the zone name, relative ratios of air flow rates passing through each zone and cross sectional areas of each air channel inlet. The distance is expressed in units of m. The air flow rate enhanced by the thermal chimney is dependent on the distance between the thermal chimney outlet and inlet.

### 1.17.13.9 Field: Relative Ratios of Air Flow Rates Passing through Zone <#>

This dimensionless number is the relative ratio of air flow rates enhanced by the thermal chimney passing through each zone. The total air flow rate enhanced by the thermal chimney is distributed to each zone based on this number if multiple zones share the common thermal chimney. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and cross sectional areas of each air channel inlet. Note that the sum of all ratios must be equal to 1.0.

### 1.17.13.10 Field: Cross Sectional Areas of Air Channel Inlet <#>

This field is the cross sectional areas of each air channel inlet corresponding to each zone. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and relative ratios of air flow rates passing through each zone. The area is expressed in units of m<sup>2</sup>. The air flow rate enhanced by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet.

## 1.17.14 ZoneThermalChimney Outputs

Current ThermalChimney output variables:

- HVAC,Average,Zone Thermal Chimney Current Density Air Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Zone Thermal Chimney Standard Density Air Volume Flow Rate [m<sup>3</sup>/s]
- HVAC,Average,Zone Thermal Chimney Mass Flow Rate [kg/s]
- HVAC,Average,Zone Thermal Chimney Outlet Temperature [C]
- HVAC,Sum,Zone Thermal Chimney Heat Loss Energy [J]
- HVAC,Sum,Zone Thermal Chimney Heat Gain Energy [J]

- HVAC,Sum,Zone Thermal Chimney Volume [m3]
- HVAC,Sum,Zone Thermal Chimney Mass [kg]

#### 1.17.14.1 Zone Thermal Chimney Heat Loss Energy [J]

The sensible (temperature) heat loss of each zone that occurs when the thermal chimney cools the zone air.

#### 1.17.14.2 Zone Thermal Chimney Heat Gain Energy [J]

The sensible (temperature) heat gain of each zone that occurs when the thermal chimney heats the zone air.

#### 1.17.14.3 Zone Thermal Chimney Volume [m3]

The air volumetric flow of each zone enhanced by the thermal chimney.

#### 1.17.14.4 Zone Thermal Chimney Mass [kg]

The air mass flow of each zone enhanced by the thermal chimney.

#### 1.17.14.5 Zone Thermal Chimney Current Density Air Volume Flow Rate [m3/s]

The total air volumetric flow rate caused by the thermal chimney evaluating density at the current zone conditions.

#### 1.17.14.6 Zone Thermal Chimney Standard Density Air Volume Flow Rate [m3/s]

The total air volumetric flow rate caused by the thermal chimney evaluating density at standard conditions.

#### 1.17.14.7 Zone Thermal Chimney Mass Flow Rate [kg/s]

The total air mass flow rate caused by the thermal chimney.

#### 1.17.14.8 Zone Thermal Chimney Outlet Temperature [C]

The temperature of the air which is discharged from the thermal chimney through the outlet.

In addition, the mass flow rate and associated sensible and latent loads are included in Zone Infiltration \* output variables. In other words, the output variables of Zone Infiltration \* include impact of ZoneThermalChimney.

### 1.17.15 ZoneAirMassFlowConservation

This global object allows users to trigger the zone air mass flow conservation calculation when desired. This object has three input fields; the first choice input field allows the user whether to adjust mixing flows, the return air flow, or a combination of mixing and return air flows to enforce the zone air mass flow conservation; and the other fields allows the user to specify how infiltration object mass flow rate is calculated for zone air mass flow balance calculation. Currently supported options are: **AdjustMixingOnly**, **AdjustReturnOnly**, **AdjustMixingThenReturn**, **AdjustReturnThenMixing**, or **None**. If adjustments for either of mixing, return, or a combination of mixing and return or infiltration is specified then the zone air mass balance attempts to enforce

conservation. If adjutement choice is None and infiltration adjustments are off, then the zone air mass flow calculation uses the default method which does not include zone mixing objects and assumes self-balanced simple infiltration. The default method may not necessarily enforce zone air mass flow conservation unless the user has specified a balanced flow to begin with. The zone air mass flow conservation primarily accounts for the zonemixing objects and return air flows in the zone air flow mass balance calculation. In addition to the zonemixing object and zone return air flows, the procedure accounts for zone supply, exhaust, and adjusts infiltration air flows (up or down) when required in order to balance the zone air mass flow. Mixing and infiltration adjustments will only be made in zones which have zonemixing or infiltration objects defined in the input. For example, if a zone does not have any infiltration objects, then no infiltration adjustment will be made for that zone.

The zone mixing object and return flows adjusting options to enforce zone air mass flow conseravtion are defined as follows. **AdjustMixingOnly** adjusts the zone mixing object flow only to enforce zone air mass flow balance. **AdjustReturnOnly** adjusts the zone return air flow only to enforce zone air mass flow balance while the zone mixing object flow are kept at user specified values. **AdjustMixingThenReturn** adjusts the zone mixing object flow first, and followed with adjusting the return air flows to enforce zone air mass flow balance. **AdjustReturnThenMixing** adjusts the zone return air flow first, and followed with adjusting the zone mixing object flow to enforce zone air mass flow balance. **None** does not adjust either the zone mixing or the zone return air flow, and the zone air mass flow balance uses the default method.

First, depending user choice either the **ZoneMixing** object mass flow rate, the zone total return air flow rate, or a combination zone mixing and zone total return flow rates are adjusted or modified in order to balance zone air mass flow while assuming any zone infiltration objects are self-balanced.

This step will always results in balanced zone air mass for receiving zones of **ZoneMixing** object but it may not necessarily result in a balanced air mass flow for source zones.

Second, infiltration flow rates are adjusted according to the options set. Infiltration flow will be increased or decreased to balance the net flow from supply, exhaust, mixing, and return air flows. If a negative infiltration rate (exfiltration) is required to balance a zone's airflow, then the infiltration rate will be set to zero. This can happen, for example, if the total supply flow exceeds the total exahust plus return flow.

This object is optional. If it is not present in the input file, the default zone air mass flow calculastion are used which do not account for zonemixing and infiltration flows.

### 1.17.15.1 Inputs

#### 1.17.15.1.1 Field: Adjust Zone Mixing and Return For Air Mass Flow Balance

This field has five choices: *AdjustMixingOnly*, *AdjustReturnOnly*, *AdjustMixingThenReturn*, *AdjustReturnThenMixing* or *None*. When set to *AdjustMixingOnly*, the zone air mass flow balance attempts to enforce zone mass flow conservation by adjusting zone mixing flow rates and zone infiltration air flow may be increased or decreased if required in order to balance the zone air mass flow. When set to *AdjustReturnOnly*, the zone air mass flow balance attempts to enforce zone mass flow conservation by adjusting zone total return air flow rates and zone infiltration air flow may be increased or decreased if required in order to balance the zone air mass flow. When set to *AdjustMixingThenReturn*, first the zone air mass flow balance attempts to enforce zone mass flow conservation by adjusting zone mixing object flow rates, then the zone total return flow rates are adjusted and zone infiltration air flow may be increased or decreased if required in order to balance the zone air mass flow. When set to *AdjustReturnThenMixing*, first the zone air mass flow balance attempts to enforce zone mass flow conservation by adjusting zone total return air flow rates, then the zone mixing flow rates are adjusted and zone infiltration air flow may be increased or decreased if required in order to balance the zone air mass flow. When set to *None*, mixing flow rates are not adjusted; the mixing flows specified in **ZoneMixing** obects will be used. The default is

*None.*

#### 1.17.15.1.2 Field: Infiltration Balancing Method

This field has three choices: *AddInfiltrationFlow*, *AdjustInfiltrationFlow*, or *None*. The default is *AddInfiltrationFlow*. With all three options, the base infiltration flow rate is the flow specified in all *Infiltration:\** objects for a given zone.

*AddInfiltrationFlow*: The base infiltration flow may be increased in order to balance the zone air mass flow. This additional infiltration air mass flow is not self-balanced, i.e., it is always assumed to be incoming flow which leaves by exhaust, mixing, or return. If no infiltration air is required in order to balance the zone air mass flow, then the additional infiltration air mass flow rate is set to zero. For this option, the base infiltration flow is always assumed to be self-balanced (i.e., exfiltration = infiltration) and is not included in the zone air mass flow balance.

*AdjustInfiltrationFlow*: The base infiltration flow may be increased or decreased in order to balance the zone air mass flow. If no infiltration is required to balance the zone air flow, then the base infiltration flow rate is retained and assumed to be self-balanced (i.e., exfiltration = infiltration). If the required infiltration flow rate is negative (exfiltration), then the infiltration flow rate is set to zero and surplus flow in the zone is assumed to leave as exfiltration.

*None*: The base infiltration flow is always assumed to be self-balanced (i.e., exfiltration = infiltration) and is not included in the zone air mass flow balance. No changes are made to the base infiltration flow rate.

#### 1.17.15.1.3 Field: Infiltration Balancing Zones

This field allows user to choose which zones are included in infiltration balancing. There are two choices: *MixingSourceZoneOnly* or *AllZones*.

*MixingSourceZonesOnly*: Infiltration balancing is active only in zones which are source zones for mixing and which have a base infiltration object defined.

*AllZones*: Infiltration balance is active in any zone which has a base infiltration object defined.

An IDF example is shown below:

```
ZoneAirMassFlowConservation,
  Yes,           !- Adjust Zone Mixing For Zone Air Mass Flow Balance
  AdjustInfiltrationFlow;   !- Infiltration Balancing Method
  AllZones;      !- Infiltration Balancing Zones
```

#### 1.17.15.2 Outputs

Current ZoneAirMassFlowConservation output variables (only applicable variables will be generated):

- HVAC, Average, Zone Air Mass Balance Supply Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Exhaust Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Return Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Mixing Receiving Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Mixing Source Mass Flow Rate [kg/s]
- HVAC, Average, Zone Infiltration Air Mass Flow Balance Status, []
- HVAC, Average, Zone Mass Balance Infiltration Air Mass Flow Rate, [kg/s]

### 1.17.15.2.1 Zone Air Mass Balance Supply Mass Flow Rate [kg/s]

This output variable represents the total supply air mass flow rate of a zone. The value is determined by summing the supply air mass flow rates contributions from all supply air inlet nodes of a zone.

### 1.17.15.2.2 Zone Air Mass Balance Exhaust Mass Flow Rate [kg/s]

This output variable represents the total exhaust air mass flow rate of a zone. The value is determined by summing the exhaust air mass flow rates contributions from all exhaust air nodes of a zone.

### 1.17.15.2.3 Zone Air Mass Balance Return Mass Flow Rate [kg/s]

This output variable represents the total return air mass flow rate of a zone. The value is determined by summing the return air mass flow rates contributions from return air nodes of a zone.

### 1.17.15.2.4 Zone Air Mass Balance Mixing Receiving Mass Flow Rate [kg/s]

This output variable represents the total zone mixing air mass flow rate of a receiving zone from one or more mixing objects. The value is determined by summing the air mass flow contributions from all zone mixing objects connected to a single receiving zone.

### 1.17.15.2.5 Zone Air Mass Balance Mixing Source Mass Flow Rate [kg/s]

This output variable represents the total zone mixing source air mass flow rate of a source zone feeding one or more mixing objects. The value is determined by summing the air mass flow contributions from all zone mixing objects connected to a single source zone.

### 1.17.15.2.6 Zone Air Mass Balance Infiltration Status []

This output variable indicates the status of the infiltration object mass flow rate use for balancing the zone mass flow at each time step. It has values of either **0** or **1**. If the value of this report variable is **0** then the zone infiltration object mass flow rate is not used in the zone mass conservation calculation, hence the infiltration rate calculated based on the user specified inputs is maintained and the infiltration rate is assumed as self-balanced for the current timestep. If the value is **1** then the zone infiltration object mass flow rate is included in the zone air mass flow balance calculation, hence the user specified infiltration rate is modified and it is considered as incoming flow to the zone, i.e., self-balanced assumption is not valid for this zone and current time step.

### 1.17.15.2.7 Zone Air Mass Balance Infiltration Mass Flow Rate [kg/s]

This output variable represents the zone infiltration air mass flow rate in kg/s. This output variable is reported only for source zones and when the zone air mass flow balance is active. Its value depends on the Infiltration Balancing Method specified. When the infiltration method is *AddInfiltrationFlow* this output represents the additional infiltration air mass flow rate added on top of the base infiltration air flow in order to balance the zone air mass flow. In this case, the base infiltration air mass flow calculated using the user specified input is assumed self-balanced. When the infiltration method is *AdjustInfiltrationFlow* and the value of “Zone Air Mass Balance Infiltration Status” is **1**, this output represents the infiltration air mass flow rate required to balance the zone air mass flow. This value could be negative if the zone supply exceeds all other outflows. If the value of “Zone Air Mass Balance Infiltration Status” is **0**, then this output is the self-balanced base infiltration flow rate for current timestep.

## 1.18 Group – Design Objects

### 1.18.1 Input for Design Calculations and Component Autosizing

#### 1.18.1.1 Overview

In order for EnergyPlus to successfully calculate zone design heating and cooling loads and air flow rates and for the program to use these results to automatically size the HVAC components a number of input objects must be present and certain object input fields must be entered.

- The input file should contain a **SimulationControl** object. The 1<sup>st</sup> field *Do Zone Sizing Calculation* should be entered as *Yes*. This will cause a zone sizing simulation to be done using all the sizing periods in the input file as weather. If there are no air or water loops in the HVAC input fields 2 and 3 can be set to *No*. If there are one or more air loops (i.e., there is at least one **AirLoopHVAC** object in the input file) then the 2<sup>nd</sup> field *Do System Sizing Calculation* should be entered as *Yes*. If there are one or more water loops (Plant Loop objects) then the 3<sup>rd</sup> field *Do Plant Sizing Calculation* should be set to *Yes*. Finally either the 4<sup>th</sup> field (*Run Simulation for Sizing Periods*) or the 5<sup>th</sup> field (*Run Simulation for Weather File Run Periods*) should be set to *Yes* in order to autosize the components and do a real simulation using the autosized components. The component autosizing calculations are done on the first pass through the HVAC system in the real simulation.
- There must be at least 2 (up to any number) **SizingPeriod** objects present. Normally one will be for summer conditions and one for winter. The summer day should normally have the field *Day Type* set to *SummerDesignDay*. The winter design day should normally have *Day Type* set to *WinterDesignDay*.
- To apply a global sizing factor include the **Sizing:Parameters** object.
- For each controlled zone in the input file there should be a corresponding **Sizing:Zone** object. Similarly for each **AirLoopHVAC** there should be a **Sizing:System** object. And for each Plant or Condenser Loop there should be a **Sizing:Plant** object. Note however that if a controlled zone has no corresponding Zone Sizing object the data from the first Zone Sizing object will be used. Thus if all the zone sizing information is the same only one Zone Sizing object need be entered.
- Only controlled zones are included in the zone and system sizing calculations. Thus for a design air flow rate to be calculated for a zone, it must contain a thermostat *even though it might not need or have a thermostat in the full simulation*. An illustration would be a three zone building with a packaged single zone system and a thermostat in one of the zones. In order for the two slave zones to be included in the design air flow calculations they must be treated as if they have a thermostat: there must be a **ZoneControl:Thermostat** for each of the slave zones.
- Some attention should be paid to schedules. In a weekly schedule object the 9<sup>th</sup> and 10<sup>th</sup> day schedules are for summer and winter design days respectively. This means that if a **SizingPeriod** object has field *Day Type* set to *SummerDesignDay* the day schedule for summer sizing periods will be in effect. Similarly if a **SizingPeriod** object has field *Day Type* set to *WinterDesignDay* the day schedule for winter sizing periods will be in effect. Some possible applications of this capability are:
  - 1) setting internal loads (lights, equipment, occupancy) to maximum all day for cooling and to zero all day for heating;
  - 2) setting heating and cooling thermostat set points to constant values (no set up or set back);
  - 3) setting heating and cooling equipment to be always on.

None of these applications are necessarily recommended but these and other uses of the special summer/winter design day schedules may prove useful for specific situations.

- Other than zone thermostat setpoints, the sizing calculations generally know nothing about the system control inputs such as setpoints and availability schedules. The user must coordinate sizing inputs with the actual simulation control inputs.
- The sizing calculations only recognize the presence of central heating and cooling coils, preheat and precool coils and reheat coils. These are assumed to deliver the various supply temperatures specified in the **Sizing:System** and **Sizing:Zone** objects. The impact of other components such as heat recovery, dehumidifiers, and pumps are not accounted for in the sizing calculations. Central supply and return fan temperature rise is taken into account in sizing the central cooling coils.

### 1.18.1.2 Component Autosizing

For autosizing to occur at the component level the user must enter the special value *autosize* in the numeric fields for which autosizing is available. Those fields can be found by looking at the Energy+.idd data dictionary file or under individual object details in this document. Fields that can be autosized are denoted with the comment *|autosizable*. The components and fields that are autosizable are listed in the following table. Note that spaces may be inserted in object names to facilitate readability.

Table 1.40: Details of Autosizable Objects/Fields

There are 3 places in the input where the user can impose sizing factors.

1. In Sizing Parameters (object: **Sizing:Parameters**), the user can specify an over-all sizing factor. This factor is applied to all the zone design loads and air flow rates resulting from the zone sizing calculations.
2. In Zone Sizing (object: **Sizing:Zone**), the user can specify a sizing factor for a specific zone. The factor is applied to the calculated zone design loads and air flow rates for the zone named in the **Sizing:Zone** object. This sizing factor overrides the global sizing factor. That is, a zone sizing factor, if specified, replaces the global sizing factor for the named zone.
3. For some plant components (basically all central chillers, boilers and cooling towers) the user can

specify a sizing factor that modifies the autosized component capacity and flow rates. These factors are applied after the application of global or zone sizing factors. They are primarily used to split the design load between multiple components. These sizing factors can change the autosizing of the associated loops and pumps. The following rules are followed the effect of plant component sizing factors on loops and pumps.

a. For supply side branches, the sizing factors of all components in series on the branch are summed and the result becomes the branch sizing factor. If there is a branch pump its autosized design flow rate is multiplied by the branch sizing factor.

b. For each loop, if the average of the branch sizing factors is less than 1, the loop sizing factor is set equal to the sum of the branch sizing factors. If the average is greater than 1, the loop sizing factor is set equal to the maximum of the branch sizing factors. The loop sizing factor is applied to the loop design flow rate (if autosized) and to the loop pump flow rate (if autosized).

### 1.18.1.3 Mixing User-Specified and Autosized Inputs

Mixed user-specified and autosized inputs can be successfully used if the following points and suggestions are followed.

1. Each component is autosized independently. Thus user input for a flow rate in one component will have no effect on other components' autosized flow rates. For instance, specifying the chilled water loop pump's rated flow rate will have no effect on the autosizing of the chiller's design evaporator flow rate or on the plant loop's autosized maximum loop flow rate.

2. Within a component it is best to autosize all inputs and enter specified values for all inputs. For example, in a chiller, if only the nominal capacity is user-specified, the autosized chilled water flow rate may not be consistent with the specified capacity.

3. Sizing information flows only from the sizing objects to the components. The sizing calculations have no knowledge of user-specified values in a component. The only exception to this rule is that plant loop sizing will collect all component design water flow rates whether autosized or user-specified.

4. If the user wants to specify a zone or system air flow rate it should be done using the **Sizing:Zone** and **Sizing:System** objects rather than done in the individual components.

5. The plant loop flow rates are sized from the total design demand of the components connected to each loop. The components demanding water need not be autosized for the plant loop autosizing to work successfully. So the user could specify all the air side components and autosize all the plant loops and plant components. Or specify the chilled water loop flow rate, chilled water pump inputs and chiller inputs and let the condenser loop and tower autosize.

### 1.18.1.4 Component Sizing Output

The results of the component autosizing calculations are reported on the *eplusout.eio* file. For each component field that has been autosized the object type, object name, field description with unit, and value are printed out as comma separated data on a line beginning with *Component Sizing*. Examples of this are shown in the Output Details and Examples document.

The complete list of objects that have autosized fields is shown in the following table. Note that spaces may be inserted in object names to facilitate readability.

Table 1.41: Complete list of Objects with autosized Fields

### 1.18.1.5 User or External Zone Design Flow Rate Inputs

In EnergyPlus the autosizing calculations start with a calculation of the zone design air flow rates using zone by zone design day simulations. The resulting zone design air flow rates and daily air flow sequences are used in the subsequent HVAC and central plant air and fluid flow design calculations and in the component autosizing calculations. The user can override or change the calculated zone design air flow rates in several ways.

- 1) The user can enter a value for *Sizing Factor* in the *Sizing:Parameters* object (see description below).
- 2) The user can specify a zone level *Zone Sizing Factor* in each *Sizing:Zone* object.
- 3) For each zone the user can input a *Cooling Design Air Flow Rate* and/or a *Heating Design Air Flow Rate* (and specify *Cooling Design Air Flow Method = Flow/Zone* and *Heating Design Air Flow Method = Flow/Zone*). These user inputs override the calculated values. The program divides the user input cooling or heating design air flow rate by the calculated values and uses the result as a zone sizing factor to multiply all the elements in the design heating and cooling air flow and load sequences. From this point the design calculations proceed as usual.

### 1.18.1.6 User or External System Design Flow Rate Inputs

Using the results of the zone design air flow rate calculation (including any user input or altered flow rates) EnergyPlus proceeds to calculate central air system flow rates and cooling and heating loads. The results of this calculation can be overridden in the following way.

For each system (*AirLoopHVAC*), in the corresponding *Sizing:System* object, specify *Cooling Design Air Flow Method* to be *Flow/System* and input a value for *Cooling Design Air Flow Rate*. Similarly for heating specify *Heating Design Air Flow Method* to be *Flow/System* and input a value for *Heating Design Air Flow Rate*.

## 1.18.2 DesignSpecification:OutdoorAir

This object allows for the outdoor air requirements to be defined in a common location for use by other objects. This object may be referenced by name from other objects (e.g., VAV terminal units, *AirTerminal:SingleDuct:ConstantVolume>NoReheat*, and *AirTerminal:SingleDuct:Mixer*) as required to identify an outdoor air quantity for use by that object. Note that a zone name is not included as an input to this zone outdoor air definition and the number of people in a zone, zone floor area, and zone volume can only be determined after this object has been referenced by another. A single zone outdoor air definition may be referenced by multiple objects to specify that the same outdoor air requirements are used by those objects *or* multiple zone outdoor air objects may be defined and referenced by other objects as needed. If multiple zone outdoor air definitions are used, each outdoor air definition must have a unique name.

### 1.18.2.1 Inputs

#### 1.18.2.1.1 Field: Name

Unique identifying name. Any reference to this name by other objects will denote that the following outdoor air requirements will be used.

#### 1.18.2.1.2 Field: Outdoor Air Method

The input must be either *Flow/Person*, *Flow/Area*, *Flow/Zone*, *AirChanges/Hour*, *Sum*, *Maximum*, *IndoorAirQualityProcedure*, *ProportionalControlBasedOnDesignOccupancy*, or *ProportionalControlBasedOnOccupancy*. The default is *Flow/Person*.

- *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the actual zone occupancy to calculate a zone outdoor air flow rate. The density of air is measured at IUPAC standard temperature and pressure.
- *Flow/Area* means that the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* and the actual zone floor area as the zone outdoor air flow rate. The density of air is measured at IUPAC standard temperature and pressure.
- *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow per Zone* as the zone outdoor air flow rate. The density of air is measured at IUPAC standard temperature and pressure.
- *AirChanges/Hour* means that the program will use the input from the field *Air Changes per Hour* and the actual zone volume (divided by 3600 seconds per hour) as the zone outdoor air flow rate.
- *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area*, *Outdoor Air Flow per Zone*, and *Air Changes per Hour* (using the associated conversions to m<sup>3</sup>/s for each field) will be added to obtain the zone outdoor air flow rate.
- *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area*, *Outdoor Air Flow per Zone*, and *Air Changes per Hour* (using the associated conversions to m<sup>3</sup>/s for each field) will be used as the zone outdoor air flow rate.
- *IndoorAirQualityProcedure* means that the program will use the other procedure defined in ASHRAE Standard 62.1-2007 to calculate the amount of outdoor air necessary in order to maintain the levels of indoor air carbon dioxide at or below the setpoint defined in the **ZoneControl:ContaminantController** object. Appendix A of the ASHRAE 62.1-2010 user's manual discusses another method for implementing CO<sub>2</sub>-based DCV in a single zone system. The last two methods of Proportional Control calculate the required outdoor air flow rate which varies in proportion to the percentage of the CO<sub>2</sub> signal range and has two choices to calculate occupancy-based outdoor air rate.
- *ProportionalControlBasedOnOccupancySchedule* uses the real occupancy at the current time step to calculate outdoor air rate.
- *ProportionalControlBasedOnDesignOccupancy* uses the design occupancy level to calculate outdoor air rate. The former choice is a good approach to estimate outdoor air rate. However, for practical applications, the zone controller usually does not have the real time occupancy information, and the design occupancy level is assumed. The latter choice is used in the design stage.

#### 1.18.2.1.3 Field: Outdoor Air Flow per Person

The design outdoor air volume flow rate per person for this zone in cubic meters per second per person, density of air measured at IUPAC standard temperature and pressure. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all **People** statements assigned to the zone. Occupancy schedule values *are not* applied during sizing calculations and *are* applied during the remainder of the simulation. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

#### 1.18.2.1.4 Field: Outdoor Air Flow per Zone Floor Area

The design outdoor air volume flow rate per square meter of floor area (units are m<sup>3</sup>/s-m<sup>2</sup>), density of air measured at IUPAC standard temperature and pressure. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*. The default value for this field is 0.

#### 1.18.2.1.5 Field: Outdoor Air Flow per Zone

The design outdoor air flow rate for this zone in cubic meters per second, density of air measured at IUPAC standard temperature and pressure. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*. The default value for this field is 0.

### 1.18.2.1.6 Field: Outdoor Air Flow Changes per Hour

The design outdoor air volume flow rate in air changes per hour, density of air measured at IUPAC standard temperature and pressure. This factor is used along with the Zone Volume and converted to cubic meters per second. This input field is used if *Outdoor Air Method* is *AirChanges/Hour, Sum* or *Maximum*. The default value for this field is 0.

### 1.18.2.1.7 Field: Outdoor Air Schedule Name

This field is the name of schedule that defines how outdoor air requirements change over time. The field is optional. If left blank, the schedule defaults to 1.0. If used, then the schedule values are multiplied by the outdoor air flow rate defined by the previous fields. The schedule values must be between 0 and 1, inclusive.

If this DesignSpecification:OutdoorAir object is referenced by a **Controller:MechanicalVentilation** object (either directly or indirectly through **Sizing:Zone**), the schedule will be applied to all types of outdoor air calculations for the corresponding zone, regardless of the System Outdoor Air Method selected. If the schedule value is zero, then the zone will be completely removed from the system outdoor air calculations.

### 1.18.2.1.8 Field: Proportional Control Minimum Outdoor Air Flow Rate Schedule Name

This field is the name of schedule that defines how minimum outdoor air requirements change over time. The field is optional. If left blank, the schedule defaults to 1.0. If used when the field System Outdoor Air Method = ProportionalControlBasedOnDesignOARate in **Controller:MechanicalVentilation**, then the schedule values are multiplied by the outdoor air flow rate.

An IDF example:

```

## 1.18.3 DesignSpecification:OutdoorAir:SpaceList

This object creates a composite outdoor air specification for a list of Spaces (ref **Space**). The individual **DesignSpecification:OutdoorAir** objects in the list are evaluated during sizing and operation at the respective Space floor area, volume, and/or occupancy and summed for a total outdoor air requirement.

### 1.18.3.1 Inputs

#### 1.18.3.1.1 Field: Name

Unique identifying name. Any reference to this name by other objects will denote that the following outdoor air requirements will be used.

### 1.18.3.1.2 Field: Space <#> Name

Reference to a [Space](#) object.

### 1.18.3.1.3 Field: Space <#> Design Specification Outdoor Air Object Name

Reference to a [DesignSpecification:OutdoorAir](#) object.

An IDF example:

```
DesignSpecification:OutdoorAir:SpaceList,
  SZ DSOA Zone 5 List,      !- Name
  Space 5 Office,          !- Space 1 Name
  SZ DSOA Zone 5 Office,   !- Space 1 Design Specification Outdoor Air Object Name
  Space 5 Conference,      !- Space 2 Name
  SZ DSOA Zone 5 Conference; !- Space 2 Design Specification Outdoor Air Object Name
```

## 1.18.4 DesignSpecification:ZoneAirDistribution

This object is used to describe the air distribution effectiveness and fraction of secondary recirculation air (return air not directly mixed with outdoor air) of a zone. It is referenced by the [Sizing:Zone](#) and [Controller:MechanicalVentilation](#) objects.

### 1.18.4.1 Inputs

#### 1.18.4.1.1 Field: Name

The unique user assigned name for an instance of this object. Any other object referencing this object will use this name.

#### 1.18.4.1.2 Field: Zone Air Distribution Effectiveness in Cooling Mode

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in cooling mode. Default value of this field is 1.0. ASHRAE Standard 62.1-2010 provides typical values.

#### 1.18.4.1.3 Field: Zone Air Distribution Effectiveness in Heating Mode

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in heating mode. Default value of this field is 1.0. ASHRAE Standard 62.1-2010 provides typical values as follows:

#### 1.18.4.1.4 Field: Zone Air Distribution Effectiveness Schedule Name

This optional field input points to a schedule with values of zone air distribution effectiveness. It provides a more flexible way of specifying zone air distribution effectiveness if it changes with time and/or system operating status and controls. If the schedule is specified, the zone air distribution effectiveness in cooling mode and heating mode will be ignored.

#### 1.18.4.1.5 Field: Zone Secondary Recirculation Fraction

The non-negative numeric input for this field is the fraction of a zone's recirculation air that does not directly mix with the outdoor air. The zone secondary recirculation fraction Er is determined by the designer based on system configuration. For plenum return systems with secondary recirculation (e.g., fan-powered VAV with plenum return) Er is usually less than 1.0, although values may range from 0.1 to 1.2 depending upon the location of the ventilation zone relative to other zones and the air handler. For ducted return systems with secondary recirculation (e.g., fan-powered VAV with ducted return), Er is typically 0.0, while for those with system-level recirculation (e.g, dual-fan dual-duct systems with ducted return) Er is typically 1.0. For other system types, Er is typically 0.75. Minimum is 0.0, and default is 0.0

Air Distribution Configuration	$E_z$
Ceiling supply of cool air.	1.0
Ceiling supply of warm air and floor return.	1.0
Ceiling supply of warm air 15°F (8°C) or more above space temperature and ceiling return.	0.8
Ceiling supply of warm air less than 15°F (8°C) above space temperature and ceiling return provided that the 150 fpm (0.8 m/s) supply air jet reaches to within 4.5 ft (1.4 m) of floor level. <b>Note:</b> For lower velocity supply air, $E_z = 0.8$ .	1.0
Floor supply of cool air and ceiling return provided that the 150 fpm (0.8 m/s) supply jet reaches 4.5 ft (1.4 m) or more above the floor. <b>Note:</b> Most underfloor air distribution systems comply with this proviso.	1.0
Floor supply of cool air and ceiling return, provided low-velocity displacement ventilation achieves unidirectional flow and thermal stratification.	1.2
Floor supply of warm air and floor return.	1.0
Floor supply of warm air and ceiling return.	0.7
Makeup supply drawn in on the opposite side of the room from the exhaust and/or return.	0.8
Makeup supply drawn in near to the exhaust and/or return location.	0.5

1. "Cool air" is air cooler than space temperature.  
 2. "Warm air" is air warmer than space temperature.  
 3. "Ceiling" includes any point above the breathing zone.  
 4. "Floor" includes any point below the breathing zone.  
 5. As an alternative to using the above values,  $E_z$  may be regarded as equal to air change effectiveness determined in accordance with ANSI/ASHRAE Standard 129<sup>17</sup> for all air distribution configurations except unidirectional flow.

Figure 1.88: Zone Air Distribution Effectiveness (Source: ASHRAE Standard 62.1-2010)

for single-path systems (also to maintain backward compatibility). For parallel fan-powered VAV systems, the secondary ventilation path only functions ( $Er > 0.0$ ) when the fans in the VAV boxes operate, which is during heating. The local ventilation path and the benefits of secondary recirculation disappear during cooling, when the local parallel fans are off ( $Er = 0.0$ ).

#### 1.18.4.1.6 Field: Minimum Zone Ventilation Efficiency

This optional input sets a minimum on the ventilation efficiency for the zone. It is only used with the Ventilation Rate Procedure (VRP), single-path method. VRP should be chosen in Sizing System, System Outdoor Air Method = Standard62.1VentilationRateProcedure. Single-path method is indicated by leaving the previous input (Zone Secondary Recirculation Fraction) blank or setting it to 0.0. If the calculated value of ventilation efficiency for a zone is less than this value, it is raised to this minimum by raising the zone minimum air flow rate. This new value for zone minimum air flow rate then overrides other defaults and inputs in **Sizing:Zone**.

An example of this in an IDF context is shown:

```
DesignSpecification:ZoneAirDistribution,
  CM DSZAD ZN_1_FLR_1_SEC_1, !- Name
  1,                      !- Zone Air Distribution Effectiveness in Cooling Mode {dimensionless}
  1,                      !- Zone Air Distribution Effectiveness in Heating Mode {dimensionless}
  ;                      !- Zone Air Distribution Effectiveness Schedule Name
```

### 1.18.5 Sizing:Parameters

This object allows the user to specify global heating and cooling sizing ratios. These ratios will be applied at the zone level to all of the zone heating and cooling loads and air flow rates. These new loads and air flow rates are then used to calculate the system level flow rates and capacities and are used in all component sizing calculations.

The user can also specify the width (in load timesteps) of a moving average window which can be used to smooth the calculated zone design flow sequences. The use of this parameter is described below.

#### 1.18.5.1 Inputs

##### 1.18.5.1.1 Field: Heating Sizing Factor

The global heating sizing ratio applied to all of the zone design heating loads and air flow rates.

##### 1.18.5.1.2 Field: Cooling Sizing Factor

The global cooling sizing ratio applied to all of the zone design cooling loads and air flow rates

##### 1.18.5.1.3 Field: Timesteps in Averaging Window

The number of load timesteps in the zone design flow sequence averaging window. The default is 1, in which case the calculated zone design flow rates are averaged over the load timestep.

The zone design air flow rate calculation is performed assuming a potentially infinite supply of heating or cooling air at a fixed temperature. Thus the calculated design air flow rate will always be able to meet any load or change in load no matter how large or abrupt. In reality air flow rates are limited by duct sizes and fan capacities. The idealized zone design flow calculation may result in unrealistically large flow rates, especially if the user is performing the sizing calculations using thermostat schedules with night setup or setback. The calculated zone design flow rates are always averaged over the load timestep. The user may want to perform a broader average to mitigate the effect of thermostat setup and setback and prevent the warm up or cool down flow rates from dominating the design flow rate calculation. Specifying the width of the averaging window allows the user to do this.

For example, if the load calculation timestep is 15 minutes and the user specifies the *Timesteps in Averaging Window* to be 4, the zone design air flows will be averaged over a time period of 1 hour. Specifying 8 would result in averaging over a 2 hour period.

### 1.18.5.2 Outputs

The sizing factors and the averaging window size are reported out on the *eplusout.eio* file. An example is:

```
! <Load Timesteps in Zone Design Calculation Averaging Window>, Value
Timesteps in Averaging Window, 1
! <Heating Sizing Factor Information>, Sizing Factor ID, Value
Heating Sizing Factor, Global, 1.3000
Heating Sizing Factor, Zone SPACE1-1, 1.3000
Heating Sizing Factor, Zone SPACE2-1, 1.3000
Heating Sizing Factor, Zone SPACE3-1, 1.3000
Heating Sizing Factor, Zone SPACE4-1, 1.3000
Heating Sizing Factor, Zone SPACE5-1, 1.3000
! <Cooling Sizing Factor Information>, Sizing Factor ID, Value
Cooling Sizing Factor, Global, 1.3000
Cooling Sizing Factor, Zone SPACE1-1, 1.3000
Cooling Sizing Factor, Zone SPACE2-1, 1.3000
Cooling Sizing Factor, Zone SPACE3-1, 1.3000
Cooling Sizing Factor, Zone SPACE4-1, 1.3000
Cooling Sizing Factor, Zone SPACE5-1, 1.3000
```

## 1.18.6 OutputControl:Sizing:Style

As described early in the document (see: EnergyPlus Output Processing), the user may select the “style” for the sizing result files (*epluszsz.<ext>*, *eplusszz.<ext>*). This object applies to all sizing output files.

```
OutputControl:Sizing:Style,
  \memo default style for the Sizing output files is comma -- this works well for
  \memo importing into spreadsheet programs such as Excel(tm) but not so well for word
  \memo processing programs -- there tab may be a better choice.  fixed puts spaces between
  \memo the "columns"
  \unique-object
A1; \field Column Separator
  \required-field
  \type choice
  \key Comma
  \key Tab
  \key Fixed
```

### 1.18.6.1 Inputs

#### 1.18.6.1.1 Field: Column Separator

For this field, the desired separator for columns is entered. “Comma” creates comma separated fields/columns in the outputs (*eplus<sizing type>.csv* files are created). “Tab” creates tab separated fields/columns in the outputs (*eplus<sizing type>.tab* files are created). “Fixed” creates space separated fields/columns in the outputs (*eplus<sizing type>.txt* files are created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel<sup>TM</sup> or other spreadsheet programs. The tab delimited files can also be viewed by text editors, word processing programs and easily converted to “tables” within those programs.

## 1.18.7 Sizing:Zone

The Sizing:Zone object provides the data needed to perform a zone design air flow calculation for a single zone. This calculation assumes a variable amount of supply air at a fixed temperature and humidity. The

information needed consists of the zone inlet supply air conditions: temperature and humidity ratio for heating and cooling. The calculation is done for every design day included in the input. The maximum cooling load and air flow and the maximum heating load and air flow are then saved for the system level design calculations and for the component automatic sizing calculations.

The Sizing:Zone object is also the place where the user can specify the design outdoor air flow rate by referencing the name of a design specification outdoor air object. This can be specified in a number of ways (ref. [DesignSpecification:OutdoorAir](#)). This data is saved for use in the system sizing calculation or for sizing zone components that use outdoor air.

The user can also place limits on the heating and design cooling air flow rates. See *Heating Design Air Flow Method* and *Cooling Design Air Flow Method* below and the explanations of the various heating and cooling flow input fields.

The user can ask the zone design calculation to take into account the effect of a Dedicated Outdoor Air System on the zone design loads and airflow rates. The design calculation will calculate the heat addition rate to the zone of an idealized SOA system and add or subtract the result from the total zone loads and flow rates.

### 1.18.7.1 Inputs

#### 1.18.7.1.1 Field: Zone Name

The name of the Zone corresponding to this Sizing:Zone object. This is the zone for which the design air flow calculation will be made using the input data of this Sizing:Zone Object.

#### 1.18.7.1.2 Field: Zone Cooling Design Supply Air Temperature Input Method

The input must be either *SupplyAirTemperature* or *TemperatureDifference*. *SupplyAirTemperature* means that the user inputs from the fields of Zone Cooling Design Supply Air Temperature will be used to determine the zone cooling design air flow rates. *TemperatureDifference* means that the user inputs from the fields of Zone Cooling Design Supply Air Temperature Difference will be used to determine the zone cooling design air flow rates.

#### 1.18.7.1.3 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone cooling design air flow rate. This field is only used when Zone Cooling Design Supply Air Temperature Input Method = **SupplyAirTemperature**. If the value entered for this parameter is less than zero, a warning message is produced so that the user will double check the input to make sure it is correct.

#### 1.18.7.1.4 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between cooling design supply air temperature and room air temperature in degrees Celsius for the zone cooling design air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone cooling design air flow rate. This field is only used when Zone Cooling Design Supply Air Temperature Input Method = **TemperatureDifference**.

#### 1.18.7.1.5 Field: Zone Heating Design Supply Air Temperature Input Method

The input must be either *SupplyAirTemperature* or *TemperatureDifference*. *SupplyAirTemperature* means that the user inputs from the fields of Zone Heating Design Supply Air Temperature will be used to determine the zone heating design air flow rates. *TemperatureDifference* means that the user inputs from

the fields of Zone Heating Design Supply Air Temperature Difference will be used to determine the zone heating design air flow rates.

#### **1.18.7.1.6 Field: Zone Heating Design Supply Air Temperature**

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone heating design air flow rate. This field is only used when Zone Heating Design Supply Air Temperature Input Method = **SupplyAirTemperature**. If the value entered for this parameter is less than zero, a warning message is produced so that the user will double check the input to make sure it is correct though other severe errors may happen before this happens. In addition, this parameter must be greater than the Zone Cooling Design Supply Air Temperature field shown above.

#### **1.18.7.1.7 Field: Zone Heating Design Supply Air Temperature Difference**

The temperature difference between heating design supply air temperature and room air temperature in degrees Celsius for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone heating design air flow rate. This field is only used when Zone Heating Design Supply Air Temperature Input Method = **TemperatureDifference**.

#### **1.18.7.1.8 Field: Zone Cooling Design Supply Air Humidity Ratio**

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone cooling design air flow rate calculation.

#### **1.18.7.1.9 Field: Zone Heating Design Supply Air Humidity Ratio**

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone heating design air flow rate calculation.

#### **1.18.7.1.10 Field: Design Specification Outdoor Air Object Name**

This alpha field specifies the name of a **DesignSpecification:OutdoorAir** object which specifies the design outdoor air flow rate for the zone.

When a choice of IndoorAirQualityProcedure is entered in the Outdoor Air Method field of the **DesignSpecification:OutdoorAir** object, the design outdoor airflow rate is calculated based on the choice of Sum in the same field.

When a choice of ProportionalControlBasedOnDesignOccupancy or ProportionalControlBasedOnOccupancyScheduled is entered, the design outdoor airflow rate is calculated based on equations specified in the "Proportional Control" section in the Engineering Reference.

#### **1.18.7.1.11 Field: Zone Heating Sizing Factor**

This input is a zone level heating sizing ratio. The zone design heating air flow rates and loads will be multiplied by the number input in this field. This input overrides the building level sizing factor input in the **Sizing:Parameters** object. And, of course, if this field is blank or zero, the global heating sizing factor from the **Sizing:Parameters** object is used.

#### **1.18.7.1.12 Field: Zone Cooling Sizing Factor**

This input is a zone level cooling sizing ratio. The zone design cooling air flow rates and loads will be multiplied by the number input in this field. This input overrides the building level sizing factor input in

the **Sizing:Parameters** object. And, of course, if this field is blank or zero, the global cooling sizing factor from the **Sizing:Parameters** object is used.

#### 1.18.7.1.13 Field: Cooling Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the zone design cooling air flow rate. *DesignDay* means the program will calculate the zone design cooling air flow rate using the *Sizing:Zone* input data and a design day simulation without imposing any limits other than those set by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Cooling Minimum Air Flow per Zone Floor Area* and *Cooling Minimum Air Flow* will set a lower limit on the design maximum cooling air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

#### 1.18.7.1.14 Field: Cooling Design Air Flow Rate

The design zone cooling air flow rate in cubic meters per second. This input is used if *Cooling Design Air Flow Method* is specified as *Flow/Zone*. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

#### 1.18.7.1.15 Field: Cooling Minimum Air Flow per Zone Floor Area

The minimum zone cooling volumetric flow rate per square meter (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, *Cooling Minimum Air Flow Fraction* and the design outdoor air flow rate (including VRP adjustments) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is 0.000762, corresponding to 0.15 cfm/ft<sup>2</sup>. The applicable sizing factor is not applied to this value.

#### 1.18.7.1.16 Field: Cooling Minimum Air Flow

The minimum zone cooling volumetric flow rate in  $\text{m}^3/\text{s}$ . This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, *Cooling Minimum Air Flow Fraction* and the design outdoor air flow rate (including VRP adjustments) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. The applicable sizing factor is not applied to this value.

#### 1.18.7.1.17 Field: Cooling Minimum Air Flow Fraction

The minimum zone design cooling volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, *Cooling Minimum Air Flow Fraction* and the design outdoor air flow rate (including VRP adjustments) is used to set a minimum supply air flow rate for the zone for VAV systems. The default is 0.2. This input is currently used in sizing the VAV air terminal unit and fan minimum flow rate. It does not currently affect other component autosizing.

#### 1.18.7.1.18 Field: Heating Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Heating Design Air Flow Rate* as the zone design heating air flow rate. *DesignDay* means the program will calculate the zone design heating air flow rate using the *Sizing:Zone* input data and a design day simulation without imposing any limits other than those set

by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Heating Maximum Air Flow per Zone Floor Area* and *Heating Maximum Air Flow* will set a lower limit on the design maximum heating air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

#### 1.18.7.1.19 Field: Heating Design Air Flow Rate

The design zone heating air flow rate in cubic meters per second. This input is used if *Heating Design Air Flow Method* is specified as *Flow/Zone*. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

#### 1.18.7.1.20 Field: Heating Maximum Air Flow per Zone Floor Area

The maximum zone heating volumetric flow rate per square meter (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. For this and the next two input fields, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.002032, corresponding to 0.40 cfm/ $\text{ft}^2$ . If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be used in calculating the maximum heating design flow rate).

#### 1.18.7.1.21 Field: Heating Maximum Air Flow

The maximum zone heating volumetric flow rate in  $\text{m}^3/\text{s}$ . This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. For this field and the two input fields just prior to and after this field, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.1415762, corresponding to 300 cfm. If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be used in calculating the maximum heating design flow rate).

#### 1.18.7.1.22 Field: Heating Maximum Air Flow Fraction

The maximum zone design heating volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. For this and the previous two input fields, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.3. If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be used in calculating the maximum heating design flow rate).

#### 1.18.7.1.23 Field: Design Specification Zone Air Distribution Object Name

The name of the **DesignSpecification:ZoneAirDistribution** object, defining the air distribution effectiveness and secondary recirculation air fraction, that applies to the zone or zone list. This

object may be used for the same zone in the `Controller:MechanicalVentilation` object if no such `DesignSpecification:ZoneAirDistribution` object is specified.

#### 1.18.7.1.24 Field: Account for Dedicated Outdoor Air System

This is a choice field with choices *Yes* or *No*. The default is *No*. Choosing *Yes* means that the zone sizing calculation will use the subsequent inputs to calculate the heat gain or loss (heat gains are positive, heat loss is negative) imposed on the zone by a Dedicated Outdoor Air System (DOAS). This heat gain is then added to the zone design heat gain for the zone and the zone design air flow rate is adjusted to meet the DOAS heat gain plus the zone design heat gain.

#### **1.18.7.1.25 Field: Dedicated Outdoor Air System Control Strategy**

This is a choice field with a choice of three ideal control strategies for the DOA system. The choices are *NeutralSupplyAir*, *NeutralDehumidifiedSupplyAir*, or *ColdSupplyAir*. The default is *NeutralSupplyAir*.

*NeutralSupplyAir* implies that the ventilation air supplied to the zone will cause little heating or cooling. The air will be heated or cooled to keep it between the low and high temperature setpoints specified in the subsequent two fields. A good choice for these fields might be 21.1 and 23.9 degrees C.

*NeutralDehumidifiedSupplyAir* means that the ventilation air will be cooled and dehumidified and then reheated to a neutral temperature. The ventilation air is cooled to the lower setpoint temperature (if necessary) and reheated to the upper setpoint temperature. A good choice for the setpoints would be 14.4 and 22.2 degrees C.

*ColdSupplyAir* means that the ventilation air will be used to supply cooling to the zone. Cold outside air is heated to the upper setpoint; warm outside air is cooled to the lower setpoint. A good choice for the setpoints would be 12.2 and 14.4 degrees C.

### 1.18.7.1.26 Field: Dedicated Outdoor Air Low Temperature Setpoint for Design

The lower setpoint temperature to be used with the DOAS design control strategy. The units are degrees C. The default is autosized to the values given above for the three design control strategies.

1.18.7.1.27 Field: Dedicated Outdoor Air High Temperature Setpoint for Design

The higher setpoint temperature to be used with the DOAS design control strategy. The units are degrees C. The default is autosized to the values given above for the three design control strategies.

### 1.18.7.2 Outputs

The zone design air flow rates and loads are output onto the local file “epluszszz.<ext>” where <ext> is the extension from the sizing style object (default is csv – a comma separated file *epluszszz.csv*). The columns are clearly labeled. It will easily import into Excel or other spreadsheet program that accepts delimited files. All of these values are design air flow rates and loads *calculated by the program*. No sizing factors have been applied.

The calculated zone design air flow rates and the user input or altered zone design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each zone as comma separated records beginning with *Zone Sizing*. Items output on the *eio* file are: zone name, load type (heating or cooling), design load, calculated design air flow rate, user design air flow rate, design day name, time of peak, outside temperature at peak, outside humidity ratio at peak.

### 1.18.8 DesignSpecification:ZoneHVAC:Sizing

This object is used to describe general sizing and scalable sizing methods which are referenced by zone HVAC equipment objects. It is optional input field in zone HVAC objects. If a name of this optional input is not specified or is blank then the sizing method or input specified in the parent object is used. If the name of this object is entered, then the values or method specified overrides the sizing method in the parent zone HVAC objects. This object is meant to provide scalable sizing method to users. The name of this object is an optional input field in the zoneHVAC objects. When this name is not specified in the zone HVAC object the sizing method or the value specified in the zone HVAC object will be used.

List of zoneHVAC objects than can reference this object include:

- ZoneHVAC:TerminalUnit:VariableRefrigerantFlow
- ZoneHVAC:PackagedTerminalAirConditioner
- ZoneHVAC:PackagedTerminalHeatPump
- ZoneHVAC:WaterToAirHeatPump
- ZoneHVAC:WindowAirConditioner
- ZoneHVAC:UnitHeater
- ZoneHVAC:UnitVentilator

- ZoneHVAC:FourPipeFanCoil
- ZoneHVAC:VentilatedSlab
- ZoneHVAC:EvaporativeCoolerUnit
- ZoneHVAC:IdealLoadsAirSystem

The sizing methods input fields available in this objects are for supply air flow and capacity for heating and cooling operating modes. Some zone HVAC equipment has single supply air flow rate input field that serves both cooling and heating operating modes. So entering either of the cooling or heating scalable sizing input field is sufficient. When there are separate input fields for cooling, heating, no-cooling, and no-heating operating modes, the corresponding input fields are specified. The child components supply air flow rate are also sized using scalable sizing methods specified in the parent objects. The methods allow users to enter a fixed or hard sized values, autosizable, or scalable sizing methods. Methods allowed for sizing supply air flow rates include: *SupplyAirFlowRate*, *FractionOfAutosizedCoolingAirflow*, *FractionOfAutosizedHeatingAirflow*, *FlowPerFloorArea*, *FlowPerCoolingCapacity*, and *FlowPerHeatingCapacity*. The different sizing options are defined as follows:

- **SupplyAirFlowRate**: entered when it is intended that the user specified either hard value or the simulation engine autosize the supply air flow rates for cooling, heating, and no-cooling or no-heating operating modes.
- **FlowPerFloorArea**: entered when it is intended that the simulation engine determine the supply air flow rates from the user specified *supply air flow rates per unit floor area* and the zone floor area of the zone served by the zone HVAC equipment.
- **FractionOfAutosizedCoolingAirflow**: entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *flow fraction* and *autosized cooling design supply air flow rate*.
- **FractionOfAutosizedHeatingAirflow**: entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *flow fraction* and *autosized heating design supply air flow rate*.
- **FlowPerCoolingCapacity**: entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *supply air flow per cooling capacity value* and *autosized cooling design capacity*.
- **FlowPerHeatingCapacity**: entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *supply air flow per heating capacity value* and *autosized heating design capacity*.

The Design Specification ZoneHVAC Sizing object also has input fields for sizing or scalable sizing of cooling and heating capacity. However, most of the parent zone HVAC objects do not have input fields for sizing capacities. So, the capacity scalable sizing fields in the parent objects are used for sizing child components capacity sizings. The scalable capacity sizing may be indirectly impacted by the scalable supply air flow rates sizing values. Moreover, the autosized cold water, hot water and steam flow rates in the parent zone HVAC objects (e.g. FanCoils, UnitHeaters, UnitVentilators, and VentilatedSlabs) and capacity in child components are determined using the scalable sizing methods. Sizing methods allowed for cooling and heating capacity include: *CoolingDesignCapacity*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, *FractionOfAutosizedCoolingCapacity*, *FractionOfAutosizedHeatingCapacity*.

- **CoolingDesignCapacity:** entered when it is intended that user specifies either a hard sized cooling capacity value or the simulation engine autosizes cooling capacity value for the cooling design capacity.
- **HeatingDesignCapacity:** entered when it is intended that user specifies either a hard sized heating capacity value or the simulation engine autosized heating capacity value for the heating design capacity.
- **CapacityPerFloorArea:** is entered when it is intended that the simulation engine determines the cooling or heating capacity from user specified capacity per floor area value and the floor area of the zone served by the zone HVAC equipment.
- **FractionOfAutosizedCoolingCapacity:** entered when it is intended that the simulation engine sizes the cooling capacity from the user specified *capacity fraction* and *autosized cooling design capacity* value.
- **FractionOfAutosizedHeatingCapacity:** entered when it is intended that the simulation engine sizes the heating capacity from the user specified *capacity fraction* and *autosized heating design capacity* value.

Description of the input fields of the design specification zone HVAC sizing object “DesignSpecification:ZoneHVAC:Sizing”

### 1.18.8.1 Inputs

#### 1.18.8.1.1 Field: Name

Unique identifier name of the DesignSpecification:ZoneHVAC:Sizing object. This sizing specification object referenced by a zone HVAC equipment whose design calculation will be made using the input data of this object.

#### 1.18.8.1.2 Field: Cooling Design Air Flow Method

The input of this field must be the method used to determine the cooling supply air volume flow rate. Input allowed is either *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *None* means cooling coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means the user specifies the magnitude of supply air flow rate or the program calculates the design cooling supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the cooling supply air volume flow rate from zone floor area served by the zone HVAC unit and user specified *Flow Per Floor Area* value. *FractionOfAutosizedCoolingAirflow* means the program calculates the cooling supply air volume flow rate from user specified fraction and the autosized design cooling supply air volume flow rate value determined by the simulation. *FlowPerCoolingCapacity* means the supply air volume is calculated from user specified flow per cooling capacity and design cooling capacity determined by the simulation. The default method is *SupplyAirFlowRate*.

#### 1.18.8.1.3 Field: Cooling Design Supply Air Flow Rate {m<sup>3</sup>/s}

Enter the magnitude of the cooling supply air volume flow rate in m<sup>3</sup>/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Cooling Design air Flow Method is *SupplyAirFlowRate*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment. This input field is also autosizable.

**1.18.8.1.4 Field: Cooling Design Supply Air Flow Rate Per Floor Area {m<sup>3</sup>/s-m<sup>2</sup>}**

Enter the cooling supply air volume flow rate per zone conditioned floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Cooling Design air Flow Method is *FlowPerFloorArea*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Air Flow Method is not *FlowPerFloorArea*. The program calculates the cooling supply air volume flow rate from the zone conditioned floor area served by the zone HVAC equipment and the flow per unit area value specified by the user. Zone sizing object ([Sizing:Zone](#)) is not required.

**1.18.8.1.5 Field: Fraction of Autosized Cooling Design Supply Air Flow Rate**

Enter the cooling supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required when the Cooling Design air Flow Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design air Flow Method is not *FractionOfAutosizedCoolingAirflow*. The program calculates the cooling supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction. Zone sizing object ([Sizing:Zone](#)) is required.

**1.18.8.1.6 Field: Cooling Design Supply Air Flow Rate Per Unit Cooling Capacity {m<sup>3</sup>/s-W}**

Enter the cooling supply air volume flow rate per unit cooling capacity in m<sup>3</sup>/s-W. This input field is required when the Cooling Design air Flow Method is *FlowPerCoolingCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design air Flow Method is not *FlowPerCoolingCapacity*. The program calculates the cooling supply air volume flow rate from the design autosized cooling capacity and user specified flow per cooling capacity value. Zone sizing object ([Sizing:Zone](#)) is required.

**1.18.8.1.7 Field: Supply Air Flow Rate Method When No Cooling or Heating is Required**

Enter the method used to determine the supply air volume flow rate when No Cooling or Heating is required. Inputs allowed are *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, and *FractionOfAutosizedHeatingAirflow*. *None* is used when a cooling or heating coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means user specifies the magnitude of supply air flow rate or the program calculates the design supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the supply air volume flow rate from the zone floor area served by the zone HVAC unit and Flow Per Floor Area value specified by user. *FractionOfAutosizedCoolingAirflow* means the program calculates the supply air volume flow rate from user specified fraction and autosized design cooling supply air volume flow rate value determined by the program. *FractionOfAutosizedHeatingAirflow* means the program calculates the supply air volume flow rate from user specified fraction and autosized heating supply air flow rate value determined by the program. The default method is *SupplyAirFlowRate*.

**1.18.8.1.8 Field: Supply Air Flow Rate When No Cooling or Heating is Required {m<sup>3</sup>/s}**

Enter the magnitude of the supply air volume flow rate when no cooling or heating is required in m<sup>3</sup>/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Supply Air Flow Rate Method When No Cooling or Heating is Required is *SupplyAirFlowRate*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment. This input field is also autosizable.

#### **1.18.8.1.9 Field: Supply Air Flow Rate Per Floor Area When No Clg or Htg is Required {m<sup>3</sup>/s-m<sup>2</sup>}**

Enter the magnitude of supply air volume flow rate per zone floor area in m<sup>3</sup>/s-m<sup>2</sup>. This input is a required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FlowPerFloorArea*. The program calculates the supply air flow rate when no cooling or heating is required from user specified flow per floor area and the zone area served by current zoneHVAC equipment.

#### **1.18.8.1.10 Field: Fraction of Design Cooling Supply Air Flow Rate When No Clg or Htg Required**

Enter the fraction of supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FractionOfAutosizedCoolingAirflow*. The program calculates the supply air flow rate when no cooling or heating is required from user specified fraction and the design cooling autosized supply air flow rate.

#### **1.18.8.1.11 Field: Fraction of Design Heating Supply Air Flow Rate When No Clg or Htg Required**

Enter the fraction of supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FractionOfAutosizedHeatingAirflow*. The program calculates the supply air flow rate when no cooling or heating is required from user specified fraction and the design heating autosized supply air flow rate.

#### **1.18.8.1.12 Field: Heating Design Air Flow Method**

The input of this field must be the method used to determine the heating supply air volume flow rate. Input allowed is either *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *None* means heating coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means the user specifies the magnitude of supply air flow rate or the program calculates the design heating supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the heating supply air volume flow rate from zone floor area served by the zone HVAC unit and user specified *Flow Per Floor Area* value. *FractionOfAutosizedHeatingAirflow* means the program calculates the heating supply air volume flow rate from user specified fraction and the autosized design heating supply air volume flow rate value determined by the simulation. *FlowPerHeatingCapacity* means the supply air volume is calculated from user specified flow per heating capacity and design heating capacity determined by the simulation. The default method is *SupplyAirFlowRate*.

#### **1.18.8.1.13 Field: Heating Design Supply Air Flow Rate {m<sup>3</sup>/s}**

Enter the magnitude of the heating supply air volume flow rate in m<sup>3</sup>/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Heating Design air Flow Method is *SupplyAirFlowRate*. This field may be left blank if a heating coil is not included in the zone HVAC equipment. This input field is also autosizable.

#### **1.18.8.1.14 Field: Heating Design Supply Air Flow Rate Per Floor Area {m<sup>3</sup>/s-m<sup>2</sup>}**

Enter the heating supply air volume flow rate per zone conditioned floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Heating Design air Flow Method is *FlowPerFloorArea*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Air Flow Method

is not *FlowPerFloorArea*. The program calculates the heating supply air volume flow rate from the zone conditioned floor area served by the zone HVAC equipment and the flow per unit area value specified by the user.

#### 1.18.8.1.15 Field: Fraction of Autosized Heating Design Supply Air Flow Rate

Enter the heating supply air volume flow rate as a fraction of the autosized heating supply air flow rate. This input field is required when the Heating Design air Flow Method is *FractionOfAutosizedHeatingAirflow*. This input field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design air Flow Method is not *FractionOfAutosizedHeatingAirflow*. The program calculates the heating supply air volume flow rate from the design autosized heating supply air flow rate and user specified fraction.

#### 1.18.8.1.16 Field: Heating Design Supply Air Flow Rate Per Unit Heating Capacity {m<sup>3</sup>/s-W}

Enter the heating supply air volume flow rate per unit heating capacity in m<sup>3</sup>/s-W. This input field is required when the Heating Design air Flow Method is *FlowPerHeatingCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Heating Design air Flow Method is not *FlowPerHeatingCapacity*. The program calculates the heating supply air volume flow rate from the design autosized heating capacity and user specified flow per unit heating capacity value.

#### 1.18.8.1.17 Field Cooling Design Capacity Method

Enter the method used to determine the cooling design capacity for scalable sizing. Input allowed is either *None*, *CoolingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedCoolingCapacity*. *None* is used when a cooling coil is not included in the Zone HVAC equipment or this field may be left blank. If this input field is left blank, then the design cooling capacity is set to zero. *CoolingDesignCapacity* means user specifies the magnitude of cooling capacity or the program calculates the design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from user specified cooling capacity per floor area and floor area of the zone served by the HVAC unit. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from user specified fraction and the auto-sized design cooling capacity. The default method is *CoolingDesignCapacity*.

#### 1.18.8.1.18 Field: Cooling Design Capacity {W}

Enter the magnitude of the cooling capacity in Watts. This input is an alternative to using the program auto-calculated cooling capacity value. This input is a required field when the Cooling Design Capacity Method is *CoolingDesignCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or alternative method is specified. This input field is autosizable. Design day sizing run must be specified.

#### 1.18.8.1.19 Field: Cooling Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the cooling capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zone served by the zone HVAC equipment and the cooling capacity per unit floor area value specified by the user.

#### 1.18.8.1.20 Field: Fraction of Autosized Cooling Design Capacity

Enter the cooling capacity as a fraction of the autosized cooling capacity. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. This input field may

be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

#### 1.18.8.1.21 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *None*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. *None* is used when a heating coil is not included in the Zone HVAC equipment or this field may be left blank. If this input field is left blank, then the design heating capacity is set to zero. *HeatingDesignCapacity* means user specifies the magnitude of heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the HVAC unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.18.8.1.22 Field: Heating Design Capacity {W}

Enter the magnitude of the heating capacity in Watts. This input is an alternative to using the program auto-calculated heating capacity value. This input is a required field when the Heating Design Capacity Method is *HeatingDesignCapacity*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or alternative method is specified. This input field is autosizable. Design day sizing run must be specified.

#### 1.18.8.1.23 Field: Heating Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the heating capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the zone HVAC equipment and the heating capacity per unit floor area value specified by the user.

#### 1.18.8.1.24 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. This input field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Capacity Method is not *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

## 1.18.9 DesignSpecification:AirTerminal:Sizing

This object modifies the sizing of an air loop terminal unit. It may be referenced by a [ZoneHVAC:AirDistributionUnit](#) object. The values specified here are applied to the base sizing results from the corresponding [Sizing:Zone](#) inputs. Any given [DesignSpecification:AirTerminal:Sizing](#) object may be used by multiple terminal units with similar characteristics.

### 1.18.9.1 Inputs

#### 1.18.9.1.1 Field: Name

Name of the design specification air terminal sizing object. This name may be referenced by a [ZoneHVAC:AirDistributionUnit](#) object.

#### 1.18.9.1.2 Field: Fraction of Design Sensible Cooling Load

The fraction of the design sensible cooling load to be met by this terminal unit. This fraction is applied after the Zone Cooling Sizing Factor (see [Sizing:Zone](#)).

#### 1.18.9.1.3 Field: Cooling Design Supply Air Temperature Difference Ratio

This ratio adjusts the supply air temperature difference used to calculate the cooling design supply air flow rate for this terminal unit.

#### 1.18.9.1.4 Field: Fraction of Design Sensible Heating Load

The fraction of the design sensible heating load to be met by this terminal unit. This fraction is applied after the Zone Heating Sizing Factor (see [Sizing:Zone](#)).

#### 1.18.9.1.5 Field: Heating Design Supply Air Temperature Difference Ratio

This ratio adjusts the supply air temperature difference used to calculate the heating design supply air flow rate for this terminal unit.

### 1.18.9.1.6 Field: Fraction of Minimum Outdoor Air Flow

The fraction of the zone minimum outdoor air requirement to be met by this terminal unit.

An IDF example:

```
DesignSpecification:AirTerminal:Sizing,
  Recirculation System A Terminal Sizing, !- Name
  0.6,                      !- Fraction of Design Cooling Load
  0.8,                      !- Cooling Design Supply Air Temperature Difference Ratio
  1.0,                      !- Fraction of Design Heating Load
  1.0,                      !- Heating Design Supply Air Temperature Difference Ratio
  0.0;                      !- Fraction of Minimum Outdoor Air Flow
```

## 1.18.10 Sizing:System

The Sizing:System object contains the input needed to perform a central forced air system design air flow, heating capacity, and cooling capacity calculation for a system serving one or more zones. The information needed consists of the outside environmental conditions and the design supply air temperatures, outdoor air flow rate, and minimum system air flow ratio.

The outside conditions come from the design days in the input. A system sizing calculation is performed for every design day in the input file and the resulting maximum heating and cooling air flow rates and capacities are saved for use in the component sizing calculations.

Supply air conditions are specified by inputting a supply air temperature for cooling, a supply air temperature for heating, and a preheat temperature.

The system sizing calculation sums the zone design air flow rates to obtain a system supply air flow rate. The design conditions and the outdoor air flow rate are used to calculate a design mixed air temperature. The temperature plus the design supply air temperatures allows the calculation of system design heating and cooling capacities.

### 1.18.10.1 Inputs

#### 1.18.10.1.1 Field: AirLoop Name

The name of the **AirLoopHVAC** corresponding to this Sizing:System object. This is the air system for which the design calculation will be made using the input data of this Sizing:System Object.

#### 1.18.10.1.2 Field: Type of Load to Size On

The user specified type of load on which to size the central system. The choices are *Sensible*, *Total* and *VentilationRequirement*. *Sensible* and *Total* mean that the central system supply air flow rate will be determined by combining the zone design air flow rates, which have been calculated to meet the zone sensible loads from the design days. *VentilationRequirement* means that the central system supply air flow rate will be determined by the system ventilation requirement. In addition *Sensible* tells the program to size the central cooling coil using entering air flow rate and air conditions at the sensible load peak; *Total* indicates that the program should size the central cooling coil at the air flow rate and conditions at the total load peak. The central heating coil is always sized at the conditions at the peak sensible heating load.

#### 1.18.10.1.3 Field: Design Outdoor Air Flow Rate

The design outdoor air flow rate in cubic meters per second. Generally this should be the minimum outdoor air flow. It is used for both heating and cooling design calculations. The assumption for cooling is that any outdoor air economizer will be closed. If *Autosize* is input the outdoor air flow rate will be taken from the sum of the zone outdoor air flow rates or calculated based on the System Outdoor Air Method selection (field below).

#### 1.18.10.1.4 Field: Central Heating Maximum System Air Flow Ratio

The ratio of the maximum system air flow rate for heating to the maximum system air flow rate. The value must be between 0 and 1. For constant volume systems the ratio should be set to 1. This ratio should be set to reflect what the user expects the system flow rate to be when maximum heating demand occurs. This ratio is used in calculating the central system heating capacity. Thus if the system is VAV with the zone VAV dampers held at minimum flow when there is a zone heating demand, this ratio should be set to the minimum flow ratio. If the zone VAV dampers are reverse action and can open to full flow to meet heating demand, this ratio should be set to 1. The default is set to 0.5, reflecting the fact that VAV dampers are typically not allowed to fully open during heating.

This field can be set to *AutoSize*. When automatically calculated, the ratio is determined from the system heating design flow rate divided by the main (which is usually the max of heating and cooling design flow rates) design flow rate. The design flow rates are also adjusted to be more accurate by examining each of the air terminals attached to the air system and summing the heating and maximum flow rates.

#### 1.18.10.1.5 Field: Preheat Design Temperature

The design air temperature exiting the preheat coil (if any) in degrees Celsius.

#### 1.18.10.1.6 Field: Preheat Design Humidity Ratio

The design humidity ratio exiting the preheat coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.18.10.1.7 Field: Precool Design Temperature

The design air temperature exiting the precooling coil (if any) in degrees Celsius.

#### 1.18.10.1.8 Field: Precool Design Humidity Ratio

The design humidity ratio exiting the precooling coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.18.10.1.9 Field: Central Cooling Design Supply Air Temperature

The design supply air temperature for cooling in degrees Celsius. This should be the temperature of the air exiting the central cooling coil.

#### 1.18.10.1.10 Field: Central Heating Design Supply Air Temperature

The design supply air temperature for heating in degrees Celsius. This can be either the reset temperature for a single duct system or the actual hot duct supply air temperature for dual duct systems. It should be the temperature at the exit of the main heating coil. This value is also used for the sizing of zone equipment (e.g., reheat coil) for the system embedded with central heating coils, but it is not used if there is no central heating coil in the system.

#### 1.18.10.1.11 Field: Type of Zone Sum to Use

If the input is *coincident* the central system air flow rate will be sized on the sum of the coincident zone air flow rates. If the input is *noncoincident* the central system air flow rate will be sized on the sum of the noncoincident zone air flow rates. The default is noncoincident.

#### 1.18.10.1.12 Field: 100% Outdoor Air in Cooling

Entering *Yes* means the system will be sized for cooling using 100% outdoor air. Entering *No* means the system will be sized for cooling using minimum outside air (the default).

**1.18.10.1.13 Field: 100% Outdoor Air in Heating**

Entering *Yes* means the system will be sized for heating using 100% outdoor air. Entering *No* means the system will be sized for heating using minimum outside air (the default).

**1.18.10.1.14 Field: Central Cooling Design Supply Air Humidity Ratio**

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central cooling coil. The default is 0.008 (kgWater/kgDryAir).

**1.18.10.1.15 Field: Central Heating Design Supply Air Humidity Ratio**

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central heating coil. This value is also used for the sizing of zone equipment (e.g., reheat coil) for the system embedded with central heating coils, but it is not used if there is no central heating coil in the system. The default is 0.008 (kgWater/kgDryAir).

**1.18.10.1.16 Field: Cooling Supply Air Flow Rate Method**

The input of this field must be the method used to determine the airloop cooling supply air volume flow rate. The input must be either, *DesignDay*, *Flow/System*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *DesignDay* means the program will calculate the system design cooling supply air volume flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the system design cooling supply air volume flow rate. *FlowPerFloorArea* means the program calculates the cooling supply air volume flow rate from zone floor area served by the airloop and user specified *Flow Per Floor Area* value. *FractionOfAutosizedCoolingAirflow* means the program calculates the cooling supply air volume flow rate from user specified fraction and the autosized design cooling supply air volume flow rate value determined by the simulation. *FlowPerCoolingCapacity* means the supply air volume is calculated from user specified flow per cooling capacity and design cooling capacity determined by the simulation. The default method is *DesignDay*: i.e., the program uses the calculated design values.

**1.18.10.1.17 Field: Cooling Supply Air Flow Rate**

The design system cooling air flow rate in cubic meters per second. This input is an alternative to using the program autocalculated value. This input is used if Cooling Supply Air Flow Rate Method is *Flow/System*. This value will *not* be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

**1.18.10.1.18 Field: Cooling Supply Air Flow Rate Per Floor Area {m<sup>3</sup>/s-m<sup>2</sup>}**

Enter the cooling supply air volume flow rate per zone conditioned floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Cooling Supply Air Flow Rate Method is *FlowPerFloorArea*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FlowPerFloorArea*. The program calculates the cooling supply air volume flow rate from the cooled floor area served by the air loop and the *Flow Per Unit Area* value specified by the user.

**1.18.10.1.19 Field: Cooling Fraction of Autosized Cooling Design Supply Air Flow Rate**

Enter the cooling supply air volume flow rate as a fraction of the airloop autosized cooling supply air flow rate. This input field is required when the Cooling Supply Air Flow Rate Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FractionOfAutosizedCoolingAirflow*. The

program calculates the cooling supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction.

#### **1.18.10.1.20 Field: Cooling Supply Air Flow Rate Per Unit Cooling Capacity {m<sup>3</sup>/s-W}**

Enter the cooling supply air volume flow rate per unit cooling capacity in m<sup>3</sup>/s-W. This input field is required when the Cooling Supply Air Flow Rate Method is *FlowPerCoolingCapacity*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FlowPerCoolingCapacity*. The program calculates the airloop cooling supply air volume flow rate from the design autosized cooling capacity and user specified *Flow Per Cooling Capacity* value.

#### **1.18.10.1.21 Field: Heating Supply Air Flow Rate Method**

The input of this field must be the method used to determine the airloop heating supply air volume flow rate. The input must be either, *DesignDay*, *Flow/System*, *FlowPerFloorArea*, *FractionOfAutosizedHeatingAirflow*, *FractionOfAutosizedCoolingAirflow* or *FlowPerHeatingCapacity*. *DesignDay* means the program will calculate the system design heating supply air volume flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Heating Design Air Flow Rate* as the system design heating supply air volume flow rate. *FlowPerFloorArea* means the program calculates the system heating supply air volume flow rate from zone floor area served by the airloop and user specified *Flow Per Floor Area* value. *FractionOfAutosizedHeatingAirflow* means the program calculates the system heating supply air volume flow rate from user specified fraction and the autosized system design heating supply air volume flow rate value determined by the simulation. *FractionOfAutosizedCoolingAirflow* means the program calculates the system heating supply air volume flow rate from user specified fraction and the autosized system design cooling supply air volume flow rate value determined by the simulation. *FlowPerHeatingCapacity* means the system heating supply air volume is calculated from user specified flow per heating capacity and design heating capacity determined by the simulation. The default method is *DesignDay*: i.e., the program uses the calculated design values.

#### **1.18.10.1.22 Field: Heating Supply Air Flow Rate**

The design system heating air flow rate in cubic meters per second. This input is an alternative to using the program autocalculated value. This input is used if Heating Supply Air Flow Rate Method is *Flow/System*. This value will *not* be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

#### **1.18.10.1.23 Field: Heating Supply Air Flow Rate Per Floor Area {m<sup>3</sup>/s-m<sup>2</sup>}**

Enter the heating supply air volume flow rate per zone conditioned floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Heating Supply Air Flow Rate Method is *FlowPerFloorArea*. This field may be left blank if a heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FlowPerFloorArea*. The program calculates the heating supply air volume flow rate from the heated or cooled floor area served by the air loop and the *Flow Per Unit Area* value specified by the user.

#### **1.18.10.1.24 Field: Heating Fraction of Autosized Heating Supply Air Flow Rate**

Enter the heating supply air volume flow rate as a fraction of the airloop autosized heating supply air flow rate. This input field is required when the Heating Supply Air Flow Rate Method is *FractionOfAutosizedHeatingAirflow*. This input field may be left blank if heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FractionOfAutosizedHeatingAirflow*. The

program calculates the heating supply air volume flow rate from the design autosized heating supply air flow rate and user specified fraction.

#### 1.18.10.1.25 Field: Heating Fraction of Autosized Cooling Supply Air Flow Rate

Enter the heating supply air volume flow rate as a fraction of the airloop autosized cooling supply air flow rate. This input field is required when the Heating Supply Air Flow Rate Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FractionOfAutosizedCoolingAirflow*. The program calculates the heating supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction.

#### 1.18.10.1.26 Field: Heating Design Supply Air Flow Rate Per Unit Heating Capacity {m<sup>3</sup>/s-W}

Enter the heating supply air volume flow rate per unit heating capacity in m<sup>3</sup>/s-W. This input field is required when the Heating Design air Flow Method is *FlowPerCoolingCapacity*. This field may be left blank if a heating coil is not included in the airloop or the Heating Design air Flow Method is not *FlowPerHeatingCapacity*. The program calculates the airloop heating supply air volume flow rate from the design autosized heating capacity and user specified *Flow Per Heating Capacity* value.

#### 1.18.10.1.27 Field: System Outdoor Air Method

The method used to calculate the system minimum outdoor air flow. The three choices are ZoneSum, Standard62.1VentilationRateProcedure (VRP), and Standard62.1SimplifiedProcedure (SP). ZoneSum sums the outdoor air flows across all zones served by the system. VRP uses the multi-zone equations defined in ASHRAE Standard 62.1 to calculate the system outdoor air flow. VRP considers zone air distribution effectiveness and zone diversification of outdoor air fractions. VRP may also adjust autosized air terminal maximum and minimum supply flow rates if needed to ensure adequate outdoor air flow rate to each zone. SP is similar to VRP and was introduced in ASHRAE Standard 62.1-2019. The main difference with VRP is that it uses a simplified approach to calculate a system's ventilation efficiency which is in turn used to calculate the system outdoor air flow. Additionally, when set to autosize, the minimum (primary) air flow (or air flow fraction) of these types of air terminals will be calculated following SP: [AirTerminal:SingleDuct:VAV:NoReheat](#) (*Constant Minimum Air Flow Fraction* or *Fixed Minimum Air Flow Fraction*), [AirTerminal:SingleDuct:VAV:Reheat](#) (*Constant Minimum Air Flow Fraction* or *Fixed Minimum Air Flow Fraction*), [AirTerminal:SingleDuct:SeriesPIU:Reheat](#) (*Minimum Primary Air Flow Fraction*), [AirTerminal:SingleDuct:ParallelPIU:Reheat](#) (*Minimum Primary Air Flow Fraction*).

#### 1.18.10.1.28 Field: Zone Maximum Outdoor Air Fraction

This positive numeric input is the zone maximum outdoor air fraction. For an air loop, when a zone requires outdoor air higher than the user specified Zone Maximum Outdoor Air Fraction, the zone supply air flow will be increased to cap the outdoor air fraction at the maximum value. This allows the system level outdoor air flow to be reduced while the total supply air flow increases. Valid values are from 0 to 1.0. Default is 1.0 which indicates zones can have 100% outdoor air maintaining backward compatibility. This input work for constant volume air systems, single and dual duct VAV systems.

#### 1.18.10.1.29 Field Cooling Design Capacity Method

Enter the method used to determine the cooling design capacity for scalable sizing. Input allowed is either *None*, *CoolingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedCoolingCapacity*. *None* is used when a cooling coil is not included in the airloop. If this input field is left blank, or *None* is specified, then the autosized design cooling capacity determined by the program is used.

*CoolingDesignCapacity* means user specifies the magnitude of cooling capacity or the program calculates the design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from user specified cooling capacity per floor area and floor area of the zones served by the airloop. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from user specified fraction and the auto-sized design cooling capacity. If the value this input field is blank or specified as None, then the next three input fields are not required. The default method is *CoolingDesignCapacity*.

#### 1.18.10.1.30 Field: Cooling Design Capacity {W}

Enter the magnitude of the cooling capacity in Watts. This input is an alternative to using the program auto-calculated cooling capacity value. This input is a required field when the Cooling Design Capacity Method is *CoolingDesignCapacity*. This field may be left blank if a cooling coil is not included in the air loop or alternative method is specified. This input field is autosizable.

#### 1.18.10.1.31 Field: Cooling Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the cooling capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zones served by the airloop and the cooling capacity per unit floor area value specified by the user.

#### 1.18.10.1.32 Field: Fraction of Autosized Cooling Design Capacity

Enter the cooling capacity as a fraction of the autosized cooling capacity. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. This input field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

#### 1.18.10.1.33 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *None*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. *None* is used when a heating coil is not included in the airloop. If this input field is left blank, then the autosized design heating capacity determined by the program is used. *HeatingDesignCapacity* means user specifies the magnitude of heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zones served by the airloop. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. If the value this input field is blank or specified as None, then the next three input fields are not required. The default method is *HeatingDesignCapacity*.

#### 1.18.10.1.34 Field: Heating Design Capacity {W}

Enter the magnitude of the heating capacity in Watts. This input is an alternative to using the program auto-calculated heating capacity value. This input is a required field when the Heating Design Capacity Method is *HeatingDesignCapacity*. This field may be left blank if a heating coil is not included in the airloop or alternative method is specified. This input field is autosizable.

#### 1.18.10.1.35 Field: Heating Design Capacity Per Floor Area {W/m<sup>2</sup>}

Enter the heating capacity per unit floor area in m<sup>3</sup>/s-m<sup>2</sup>. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a heating coil is not included in the airloop or the Heating Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zones served by the airloop and the heating capacity per unit floor area value specified by the user.

#### 1.18.10.1.36 Field: Fraction of Autosized Heating Design Capacity

Enter the heating capacity as a fraction of the autosized heating capacity. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. This input field may be left blank if heating coil is not included in the airloop or the Heating Design Capacity Method is not *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized cooling capacity and user specified fraction.

#### 1.18.10.1.37 Field: Central Cooling Capacity Control Method

Specifies how the central cooling coil will be controlled, which affects the coil sizing calculation. There are 4 choices: VAV, Bypass, VT, and OnOff. Choose VAV if the cooling output is controlled by varying the air flow. Bypass should be chosen if the capacity is controlled by bypassing a variable fraction of the mixed air around the coil face. VT indicates that cooling coil output is controlled by varying the coil exit temperature while the flow rate is constant. And OnOff means that the cooling output is controlled by cycling the air flow.

#### 1.18.10.1.38 Field: Occupant Diversity

The Occupant Diversity (D) as defined in ASHRAE Standard 62.1. The Occupant Diversity is a ratio of the expected peak population to the design zone population for all zones attached to the air system. If left blank or set to autosize, EnergyPlus will calculate it by using the people schedules and design levels included in the model.

An IDF example:

```

### 1.18.10.2 Outputs

The system design air flow rates and heating and cooling capacities are output onto the local file “eplusszz.<ext>” where <ext> is the extension from the sizing style object (default is csv – a comma separated file *eplusszz.csv*). The columns are clearly labeled. It will easily import into Excel or other spreadsheet program that accepts delimited files. The results are calculated values and do not include any user input system flow rates.

The calculated system design air flow rates and the user input system design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each system as comma separated records beginning with *System Sizing*. An example is:

```

! <System Sizing Information>c++, System Name, Field Description, Value
System Sizing, VAV SYS 1, Calculated Cooling Design Air Flow Rate [m3/s], 1.3194
System Sizing, VAV SYS 1, User Cooling Design Air Flow Rate [m3/s], 1.5000
System Sizing, VAV SYS 1, Calculated Heating Design Air Flow Rate [m3/s], 0.90363
System Sizing, VAV SYS 1, User Heating Design Air Flow Rate [m3/s], 1.0000

```

---

## 1.18.11 Sizing:Plant

The Sizing:Plant object contains the input needed for the program to calculate plant loop flow rates and equipment capacities when autosizing. This information is initially used by components that use water for heating or cooling such as hot or chilled water coils to calculate their maximum water flow rates. These flow rates are then summed for use in calculating the Plant Loop flow rates.

The program will size any number of chilled water, hot water, condenser water and other plant loops. There should be one Sizing:Plant object for each plant loop that is to be autosized.

### 1.18.11.1 Inputs

#### 1.18.11.1.1 Field: Plant or Condenser Loop Name

The name of a Plant Loop or Condenser Loop object corresponding to this Sizing:Plant object. This is the plant loop for which this data will be used for calculating the loop flow rate.

#### 1.18.11.1.2 Field: Loop Type

The possible inputs are *Heating*, *Steam*, *Cooling*, or *Condenser*.

#### 1.18.11.1.3 Field: Design Loop Exit Temperature

The water temperature in degrees Celsius at the exit of the supply side of the plant loop. Thus this is the temperature of the water supplied to the inlet of chilled or hot water coils and other equipment that places loads on a plant loop.

#### 1.18.11.1.4 Field: Loop Design Temperature Difference

The design temperature rise (for cooling or condenser loops) or fall (for heating loops) in degrees Celsius across the demand side of a plant loop. This temperature difference is used by component models to determine flow rates required to meet design capacities. Larger values lead to smaller design flow rates.

### 1.18.11.1.5 Field: Sizing Option

This field is optional. This field controls how concurrence issues impact the plant loop design flow rate. If it is not used then the program uses noncoincident method, which is the historical behavior prior to version 8.3. There are two choices, noncoincident and coincident. The use of Coincident sizing option requires that the **SimulationControl** object be set to YES for the input field called Do HVAC Sizing Simulation for Sizing Periods.

### 1.18.11.1.6 Field: Zone Timesteps in Averaging Window

This field is optional and is only used if the preceding field is set to Coincident. This is the number of zone timesteps used in a moving average to determine the design flow rate from HVAC Sizing Simulation approach. This allows using a broader average over time when using coincident plant sizing. This is similar in concept to the similar field in **Sizing:Parameters** which specifies the averaging window for zone loads. The default is 1.

### 1.18.11.1.7 Field: Coincident Sizing Factor Mode

This field is only used if the sizing option is set to Coincident. This field controls the behavior of coincident sizing with respect to what, if any, sizing factor should be applied to further modify the flow rate measured while running HVAC Sizing Simulations. There are four options. Enter the keyword None to use the raw value for flow rate without modification. Enter the keyword GlobalHeatingSizingFactor to modify the flow by the sizing factor entered in the object called **Sizing:Parameters** for heating. Enter the keyword GlobalCoolingSizingFactor to modify the flow by the sizing factor entered in the object called **Sizing:Parameters** for cooling. Enter the keyword LoopComponentSizingFactor to modify the flow by a sizing factor determined from the combination of component-level sizing factors in the associated plant loop.

An IDF example:

```

Sizing:Plant,
  Chilled Water Loop, ! name of loop
  Cooling,           ! type of loop
  7.22,              ! chilled water supply temperature
  6.67,              ! chilled water delta T
NonCoincident,      !- Sizing Option
1,                  !- Zone Timesteps in Averaging Window
GlobalCoolingSizingFactor; !- Coincident Sizing Factor Mode

```

## 1.18.11.2 Outputs

The loop flow rates are reported on the *eplusout.eio* file along with the component sizing results.

When coincident plant sizing method is used, the eio file contains special summary report with various details and interim values from the calculations, under the following record header: ! , Plant Loop Name, Sizing Pass {#}, Measured Mass Flow{kg/s}, Measured Demand {W}, Demand Calculated Mass Flow{kg/s}, Sizes Changed {Yes/No}, Previous Volume Flow Rate {m<sup>3</sup>/s}, New Volume Flow Rate {m<sup>3</sup>/s}, Demand Check Applied {Yes/No}, Sizing Factor {}, Normalized Change {}, Specific Heat{}.

## 1.19 HVAC: Primary and Secondary Systems

The HVAC and equipment section of the EnergyPlus input data dictionary and input data file are slightly more complex than the description of building geometry, internal gains, etc. because of the interconnections of the various parts of an HVAC system. In EnergyPlus, there are several portions to the HVAC simulation. All of these parts must be correctly specified in order to arrive at a valid simulation model. The goal of

this section is to provide interface developers and advanced users with guidelines on what input is expected and also provide some background on basic EnergyPlus simulation methodology.

An EnergyPlus HVAC simulation consists of various components that are connected physically in the actual system by ducts, piping, etc. Every component in an HVAC system must have an inlet and outlet “node”. In the actual system, a node might be a point in the system at which fluid properties can be measured. In an EnergyPlus simulation, the nodes are points at which fluid properties are evaluated and passed on to subsequent equipment.

Components are linked together to form various loops within the simulation. Thus, the output node from one component also serves as the inlet node to the next component. Loops are constructed by defining these loops and also defining the components on the loops. The figure below shows a generic example of the loop-node concept.

Loop nodes are a key defining feature in EnergyPlus. As a result, it is recommended that one of the first steps taken in defining an HVAC system in EnergyPlus be the definition of a node diagram or map. This is helpful for visualization of the entire system. Such a map could be created electronically within an interface or could be kept in the background out of the sight of the user.

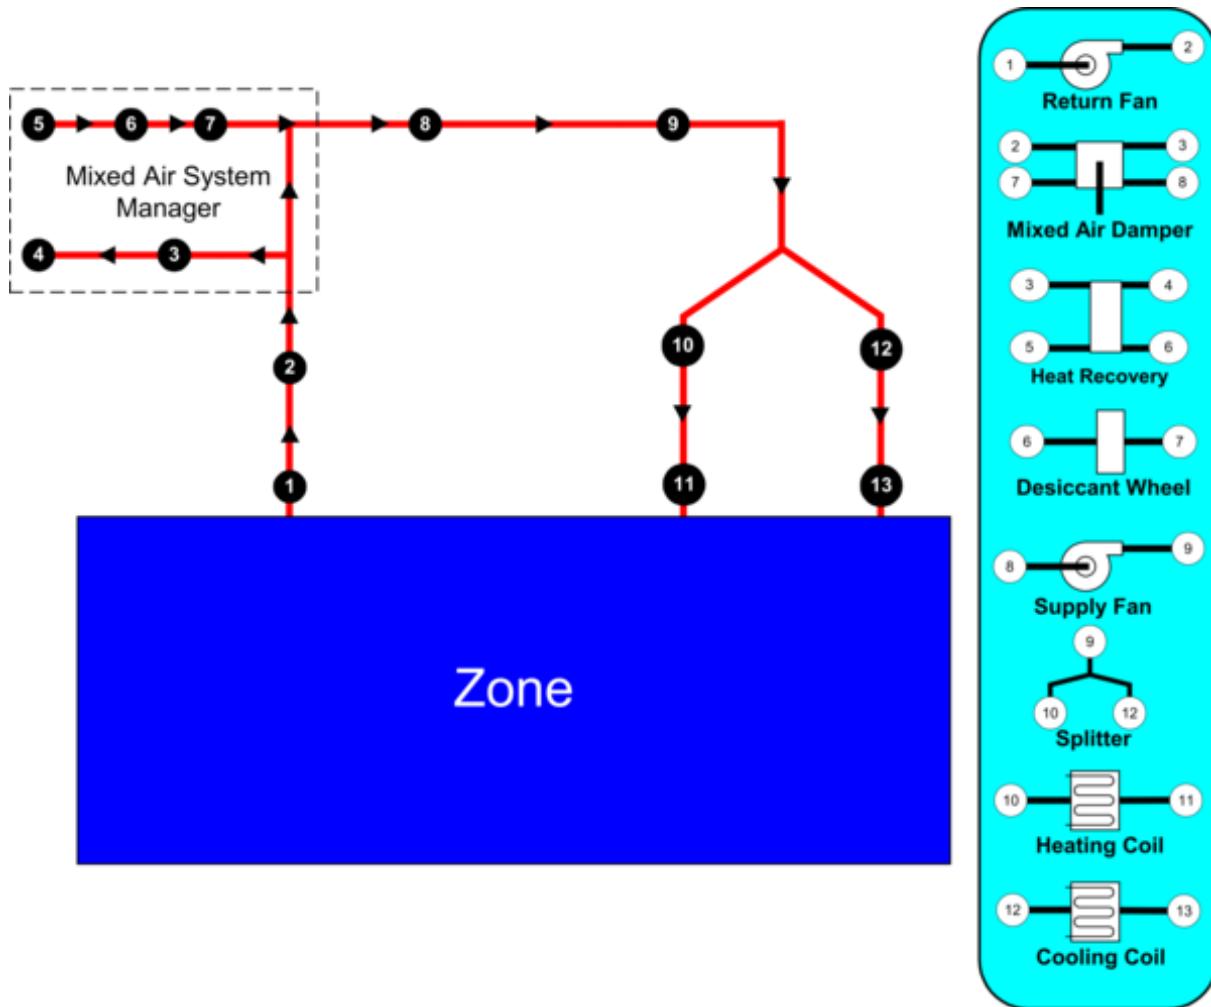

Figure 1.89: Example Node Diagram

So that these loops are manageable and more clearly defined both in the input and in the simulation, four different loop sections can be defined in an EnergyPlus input file. In general, these four types are in

essence two pairs of loop sections that make up two distinct types of loops: a zone/air loop and a plant loop. As of Version 7, plant loops and condenser loops have been consolidated to be largely the same. The four loop section types are defined below.

**Air Loop Supply Side:** The air loop is defined by the section of the zone/air loop that starts after the zone return streams are combined and continues on until just before any air stream(s) are branched off to individual zones. The starting point of the air loop is fairly straightforward. The ending point is slightly more complex but can be understood with some examples. For instance, in a terminal reheat system, the end of the air loop would typically be considered the node following the cooling coil. In a dual duct system, the air loop would have two ending points that would correspond to the nodes after the cooling coil and after the heating coil/humidifier. In most cases, the air loop has a single starting point and up to two ending points (for a 2 deck system). An outdoor air subsystem can be included in the supply side for ventilation and relief air.

**Air Loop Zone Equipment:** The zone equipment section of the input file is defined as more or less the rest of the zone/air loop (outside air is handled separately as a subset of the air loop). This includes everything from where the ducts are split to serve various zones up through where the return ducts from various zones are mixed into a single return duct. Zone equipment can include dampers and reheat coils as well as zone specific conditioning systems such as thermostatic baseboard or a window air conditioner. Most control issues are typically dealt with in the zone equipment section of the simulation.

**Plant Loop Demand Side:** One side of the plant is where energy is “demanded” by various components that make up the air loop or zone equipment. Typically, this is the water side of equipment such as coils, baseboard, radiant heating and cooling, etc. In the case of a condenser loop, energy is typically “demanded” by a chiller condenser or other water source heat pump. The demand side of this loop can also include mixers, flow splitters, and a bypass.

**Plant Loop Supply Side:** The other side of the plant loop is where energy is “supplied” by various components. The components typically found on the supply side include pumps, boilers, chillers, purchased heating and cooling, ice storage, etc. In the case of a condenser, the components would be cooling tower, fluid cooler, or ground source heat exchanger, etc. As with the demand side, this loop can also include mixers, flow splitters, and a bypass.

The section of the input file for describing the HVAC system tends to follow this structure presented above. Both plant and condenser loops are defined with a master description and then branch off into supply and demand side details. Linkage between the two sides is done using node names in the master statement. The air loop and zone equipment descriptions are slightly more complex due to the wide range of potential systems that are anticipated. Note that in every section controls become a key element and must be addressed. Each of the following sections details either a loop, a portion of a loop, or controls.

## 1.20 Group – Node-Branch Management

Nodes, Branch Lists and Branches define the topography of the HVAC connections.

### 1.20.1 NodeList

For convenience, the NodeList object can be used to identify all the nodes for a particular use. A node list is not always required. The advantage of listing all the nodes in this manner is that input fields in other objects that ask for a node name can refer to either a single node or a list of nodes using this object.

There are other lines of input syntax that require the use of a NodeList as part of the input. These syntax items include: [OutdoorAir:NodeList](#) and the SetpointManager objects. In these two cases, the use of a NodeList statement is mandatory if there is more than one node in this particular “list”. For example, if the outside air only has a single inlet node, then the name of that node can replace the node list name

in the input syntax. As a result of this mandatory specification of node lists for certain types of input, nodes can, obviously, and may be members of more than one list.

### 1.20.1.1 Inputs

#### 1.20.1.1.1 Field: Name

This alpha designation must be unique among all the Node List Names. It is used as reference in various objects (e.g. **OutdoorAir:NodeList**).

#### 1.20.1.1.2 Field: Node <#> Name (up to 25 allowed)

Each unique Node identifier creates a Node structure with various attributes depending on the type of node. Typical values include Temperature, Mass Flow Rate, and Temperature Set Point. The alpha designators are associated with a particular node.

Though each NodeList is limited to 25 nodes, several node lists may be entered if you choose to identify all the nodes up front. For example:

```
NodeList, Nodes1-25,
NODE_1,NODE_2,NODE_3,NODE_4,NODE_5,NODE_6,NODE_7,NODE_8,NODE_9,NODE_10,
NODE_11,NODE_12,NODE_13,NODE_14,NODE_15,NODE_16,NODE_17,NODE_18,NODE_19,NODE_20,
NODE_21,NODE_22,NODE_23,NODE_24,NODE_25;
NodeList, Nodes26-49,NODE_26,NODE_27,NODE_28,NODE_29,NODE_30,
NODE_31,NODE_32,NODE_33,NODE_34,NODE_35,NODE_36,NODE_37,NODE_38,NODE_39,NODE_40,
NODE_41,NODE_42,NODE_43,NODE_44,NODE_45,NODE_46,NODE_47,NODE_48,NODE_49;
```

### 1.20.1.2 Outputs

A simple detail of Nodes and numbers assigned appears in the **eplusout.bnd** file:

```
! <Node>,<NodeNumber>,<Node Name>,<Node Fluid Type>,<\# Times Node Referenced After Definition>
Node,1,OUTSIDE AIR INLET NODE 1,Air,2
Node,2,VAV SYS 1 INLET NODE,Air,3
Node,3,MIXED AIR NODE 1,Air,5
Node,4,MAIN COOLING COIL 1 OUTLET NODE,Air,3
Node,5,MAIN HEATING COIL 1 OUTLET NODE,Air,4
Node,6,VAV SYS 1 OUTLET NODE,Air,7
```

In addition, properties of each node is available during the simulation:

- HVAC,Average,System Node Temperature [C]
- HVAC,Average,System Node Last Timestep Temperature [C]
- HVAC,Average,System Node Mass Flow Rate [kg/s]
- HVAC,Average,System Node Humidity Ratio [kgWater/kgDryAir]

- HVAC,Average,System Node Height [m]
- HVAC,Average,System Node Specific Heat [J/kg-K]

**The following node variable is also available for system nodes that are for “air”:**

- HVAC, Average, System Node Current Density Volume Flow Rate [m<sup>3</sup>/s]
- HVAC, Average, System Node Current Density [kg/m<sup>3</sup>]

**The following node variables are “advanced” and normally used for debugging unusual cases:**

- HVAC,Average,System Node Minimum Temperature [C]
- HVAC,Average,System Node Maximum Temperature [C]
- HVAC,Average,System Node Minimum Limit Mass Flow Rate [kg/s]
- HVAC,Average,System Node Maximum Limit Mass Flow Rate [kg/s]
- HVAC,Average,System Node Minimum Available Mass Flow Rate [kg/s]
- HVAC,Average,System Node Maximum Available Mass Flow Rate [kg/s]
- HVAC,Average,System Node Requested Mass Flow Rate [kg/s]
- HVAC,Average,System Node Setpoint Mass Flow Rate [kg/s]

**The following node variable reports node carbon dioxide concentration when carbon dioxide is simulated (ref. ZoneAirContaminantBalance):**

- HVAC,Average,System Node CO2 Concentration [ppm]

**The following node variable reports node generic contaminant concentration when generic contaminant is simulated (ref. ZoneAirContaminantBalance):**

- HVAC,Average,System Node Generic Air Contaminant Concentration [ppm]

#### 1.20.1.2.1 System Node Temperature [C]

The current temperature at a system node in degrees C. For air nodes, this is the dry-bulb temperature.

**1.20.1.2.2 System Node Last Timestep Temperature [C]**

The temperature at a system node for the previous timestep.

**1.20.1.2.3 System Node Mass Flow Rate [kg/s]**

The current mass flow rate at a system node in kg/s.

**1.20.1.2.4 System Node Humidity Ratio [kgWater/kgDryAir]**

The current humidity ratio at a system node in kg-water/kg-dry-air. Not applicable for liquid nodes.

**1.20.1.2.5 System Node Setpoint Temperature [C]**

The current setpoint temperature at a system node in degrees C. Some controllers and equipment types sense this single setpoint.

**1.20.1.2.6 System Node Setpoint High Temperature [C]**

The current upper setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

**1.20.1.2.7 System Node Setpoint Low Temperature [C]**

The current lower setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

**1.20.1.2.8 System Node Setpoint Humidity Ratio [kgWater/kgDryAir]**

The current humidity ratio setpoint at a system node in kg-water/kg-dry-air. Some controllers and equipment types sense this single setpoint. Not applicable for liquid nodes.

**1.20.1.2.9 System Node Setpoint Minimum Humidity Ratio [kgWater/kgDryAir]**

The current minimum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

**1.20.1.2.10 System Node Setpoint Maximum Humidity Ratio [kgWater/kgDryAir]**

The current maximum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

**1.20.1.2.11 System Node Relative Humidity [%]**

The current relative humidity (calculated from the node temperature, node humidity ratio and standard barometric pressure for the location). Not applicable for liquid nodes.

**1.20.1.2.12 System Node Pressure [Pa]**

The current pressure at a system node in Pa.

**1.20.1.2.13 System Node Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

The current volume flow rate at a system node in m<sup>3</sup>/s. This report is calculated from the mass flow using standardized values for density that do not vary over time (except for steam which varies with quality). For water nodes this density is determined at a temperature of 5.05°C. For air nodes this density is determined for dry air at the standard barometric pressure for the location's elevation, and a temperature of 20.0°C. For air nodes, also see the report "System Node Current Density Volume Flow Rate."

**1.20.1.2.14 System Node Enthalpy [J/kg]**

The current enthalpy at a system node in J/kg.

**1.20.1.2.15 System Node Last Timestep Enthalpy [J/kg]**

The enthalpy at the system node for the previous timestep in Joules per kilogram.

**1.20.1.2.16 System Node Wetbulb Temperature [C]**

The current wet-bulb temperature at a system node in degrees C. Not applicable for liquid nodes.

**1.20.1.2.17 System Node Dewpoint Temperature [C]**

The current dewpoint temperature at a system node in degrees C. It is calculated from the System Node Temperature, the System Node Humidity Ratio and the Site Outdoor Air Barometric Pressure. Not applicable for liquid nodes.

**1.20.1.2.18 System Node Quality []**

The current system node vapor fraction/percent {0.0-1.0}.

**1.20.1.2.19 System Node Height [m]**

The current system node height {m}. Only applicable to outdoor air nodes.

**1.20.1.2.20 System Node Specific Heat [J/kg-K]**

The current specific heat capacity of the fluid at the node in units of J/kg-K. Not available for steam nodes.

**Additional Node Reporting for Air Nodes**

The following system node variable is available for nodes with a fluid type of air.

**1.20.1.2.21 System Node Current Density Volume Flow Rate [m<sup>3</sup>/s]**

The current volume flow rate at a system node in m<sup>3</sup>/s based on the current density. This report differs from the one called "System Node Standard Density Volume Flow Rate" in that it uses an air density calculated for the current moist air conditions rather than a standard density.

**1.20.1.2.22 System Node Current Density [kg/m3]**

The current air density at a system node in kg/m<sup>3</sup>. This is the density used to calculate the volume flow rate above. The density is calculated using current outdoor air barometric pressure and the drybulb temperature and humidity ratio at the air node.

**Advanced Node Reporting**

The following system node variables are available when you request "Diagnostics, DisplayAdvancedReportVariable". They are normally used for debugging unusual system cases and may not be available for all systems. Also, their definitions may change based on the usage in the system.

**1.20.1.2.23 System Node Minimum Temperature [C]****1.20.1.2.24 System Node Maximum Temperature [C]**

These node variables represent the min/max of loops or branches.

**1.20.1.2.25 System Node Minimum Limit Mass Flow Rate [kg/s]****1.20.1.2.26 System Node Maximum Limit Mass Flow Rate [kg/s]**

These node variables hold the maximum possible and the minimum allowable flow rates for a particular component. As such, they represent the “hardware limit” on the flow rate for the component. By convention, these variables are stored at the component inlet node. Since components share their nodes (the outlet node of one component is the inlet node of the next component), the protocol must be strictly followed. These variables are set by each component based on the design flow limits of the equipment.

**1.20.1.2.27 System Node Minimum Available Mass Flow Rate [kg/s]****1.20.1.2.28 System Node Maximum Available Mass Flow Rate [kg/s]**

These node variables represent the *loop* or *branch* maximum and minimum flow rate for the current configuration of the loop on which the component resides. The central plant routines manage these variables dynamically to resolve flow rates through branches located inside splitters and mixers.

**1.20.1.2.29 System Node Setpoint Mass Flow Rate [kg/s]**

The current mass flow rate setpoint at a system node in kg/s. Some controllers and equipment types sense this single setpoint.

**1.20.1.2.30 System Node Requested Mass Flow Rate [kg/s]**

This output is the current mass flow rate request at a system node in kg/s. Only used for plant simulations and nodes. This is the mass flow rate “requested” by a component. This is a record of what the component wanted which can be useful for diagnostics when the actual simulated flow is different than expected. This value is also used to determine overall loop flow rates.

**1.20.1.2.31 System Node CO2 Concentration [ppm]**

The average carbon dioxide concentration, in parts per million (ppm), at a system node for the timestep being reported.

**1.20.1.2.32 System Node Generic Air Contaminant Concentration [ppm]**

The average generic contaminant concentration, in parts per million (ppm), at a system node for the timestep being reported.

**1.20.2 BranchList**

A branch list is intended to define the branches or portions of a particular loop that are present on an individual plant or condenser loop. Thus, the BranchList syntax simply provides a list of branch names (see Branch syntax) that then refer to more detailed syntax in another part of the input file. The syntax for describing a list of branches is given below.

Branches in BranchList objects should be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches (within a splitter/mixer) are simulated in the order listed.

### 1.20.2.1 Inputs

#### 1.20.2.1.1 Field: Name

A unique name to identify the branch list.

#### 1.20.2.1.2 Field: Branch <#> Name

Branch name in the list. As noted above, Branches in BranchList objects MUST be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches are simulated in the order listed.

An example of this statement in an IDF is:

```
BranchList, Cooling Supply Side Branches,  
    CW Pump Branch,  
    Little Chiller Branch,  
    Big Chiller Branch,  
    Purchased Cooling Branch,  
    Supply Bypass Branch,  
    Cooling Supply Outlet;
```

### 1.20.2.2 Outputs

No output directly related to Branch Lists current is presented.

## 1.20.3 Branch

Branches can be considered the mid-level grouping of items in the EnergyPlus HVAC loop scheme. Components are the lowest level of information. A collection of components in series forms a branch. Every branch must have at least one component, but it may have several components in series. The air loop also has “unitary” objects that are compound objects that wrap components and when they are used it is the unitary objects that appear on the Branch and not the child components. The **Branch** defines the order that components appear on the branch. Moreover, a collection of branches and their connecting information form a loop. Therefore, a branch is a collection of components while a loop is a collection of branches. Thus, components are specified for particular HVAC loops by assigning them to branches and then connecting those branches together to form a loop.

For hydronic plant systems, the Branch object is used on both the demand side and the supply side of the plant loop. For HVAC air systems, the Branch object is only used to describe the components on the supply side of an air loop. The demand side of the air loop does not use the Branch object. The outside air system appears on a Branch object but it does not use a Branch object itself to describe the components that included in the outside air system. So-called “ZoneHVAC:” equipment, HVAC equipment directly associated with a zone, do not use the Branch object.

It should be noted that each component also has at least two nodes associated with it—an inlet node and an outlet node. These nodes, by default, are also part of the branch to which their components are assigned. Although it may appear redundant to list the node names in both the Branch and in the component object being referenced, this is needed because many components are connected to more than one loop at a time and the node names are needed here to distinguish which portion of the component is being attached to this particular branch and its loop. It should be noted that each branch must have at least one component on it. A “null” branch such as one where the first component on the loop is in reality a splitter or mixer should be defined as a single Pipe component for plant, or a single Duct component for air systems.

### 1.20.3.1 Inputs

#### 1.20.3.1.1 Field: Name

This alpha field is the unique, user-defined name that allows the branch to be referenced by other elements such as the **PlantLoop** and **CondenserLoop** statements.

#### 1.20.3.1.2 Field: Pressure Drop Curve Name

This is an optional field used to specify pressure drop information for this particular branch. Currently this is only available in plant/condenser fluid loops: **PlantLoop** and **CondenserLoop**. Air loops require a full airflow network, so this field is ignored if found on an air loop. The value entered for this field must match a pressure curve object also found in the input. This curve can be of the type: **Curve:Linear**, **Curve:Quadratic**, **Curve:Cubic**, **Curve:Exponent**, or **Curve:Functional:PressureDrop**. In order to then perform a pressure simulation for the loop that this branch is located on, a flag must be set in the loop object. Reference the **PlantLoop** and **CondenserLoop** field “Pressure Simulation Type” for allowable settings. See the Engineering Reference document for further information on pressure simulation in plant loops.

#### 1.20.3.1.3 Field Set (Branch Specifications)

Following the two introductory items, there are groups of 4 repeated items: a type, a name, inlet and outlet node names. All of these items refer to one particular component on the branch. The first component defined by these items will be the first component on this branch, etc. through the end of the list. This object is extensible and can use as many field sets as needed by repeating the last four fields.

#### 1.20.3.1.4 Field: Component <#> Object Type

This field is the component object type (object class name). The component type refers to other elements within the input file and specifies what kind of component this is. The objects in the Group – Plant Equipment section are valid here when the Branch is used in Plant specifications. Fans, coils, unitary systems, and Outside Air Systems are also valid component types for the Branch object. Pipes or Ducts are also valid for this field. No splitter or mixer type objects are allowed.

#### 1.20.3.1.5 Field: Component <#> Name

The component name is the unique, user-defined reference name to distinguish between potentially multiple occurrences of a particular component type in an input file. The set of component type and component name must be unique. (You can only have 1 Boiler object with name MYBOILER).

#### 1.20.3.1.6 Field: Component <#> Inlet Node Name

This field references an inlet node name that will be found in the actual component specification. The inlet node, and the outlet node specified in the next field, should correspond to component model’s connections that are intended for the loop that this Branch is assigned to. For example a water-cooled chiller will have two inlet nodes, one for chilled water return and one for condenser water return and so the chiller will appear on two Branch objects accordingly.

#### 1.20.3.1.7 Field: Component <#> Outlet Node Name

This field references an outlet node name that will be found in the actual component specification.

An example of this statement in an IDF is:

```
Branch,
  Air Loop Main Branch,      !- Branch Name
  ,                         !- Pressure Drop Curve Name
  AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass, !- Compi Type
```

```

GasHeat CBVAV System,      !- Comp1 Name
Air Loop Inlet Node,      !- Comp1 Inlet Node Name
Air Loop Outlet Node;    !- Comp1 Outlet Node Name

```

And a more complex one:

```

BRANCH,
  Air Loop Main Branch,      !- Branch Name
  ,                         !- Pressure Drop Curve Name
  FAN:ConstantVolume,        !- Comp1 Type
  Supply Fan 1,             !- Comp1 Name
  Air Loop Inlet Node,      !- Comp1 Inlet Node Name
  Cooling Coil Air Inlet Node, !- Comp1 Outlet Node Name
  COIL:Water:DetailedFlatCooling, !- Comp2 Type
  Detailed Cooling Coil,   !- Comp2 Name
  Cooling Coil Air Inlet Node, !- Comp2 Inlet Node Name
  Air Loop Outlet Node;    !- Comp2 Outlet Node Name

```

### 1.20.3.2 Outputs

The components on a branch are in series and that list is in simulation and connection order. Each branch must obey the rules: the outlet for component 1 has to have the same node name as the inlet for component 2, and so forth.

Eplusout.err contains the test for “individual branch integrity”:

```

***** Testing Individual Branch Integrity
***** Testing Branch = AIR LOOP MAIN BRANCH
***** ....passed
***** Testing Branch = COOLING DEMAND INLET
***** ....passed
***** Testing Branch = COOLING COIL BRANCH
***** ....passed
***** Testing Branch = DEMAND BYPASS BRANCH
***** ....passed
***** Testing Branch = COOLING DEMAND OUTLET
***** ....passed
***** Testing Branch = COOLING SUPPLY OUTLET
***** ....passed

```

The addition of pressure simulation for branches in fluid loops brings a new output at the branch level:

- HVAC,Average,Plant Branch Pressure Difference [Pa]

#### 1.20.3.2.1 Plant Branch Pressure Difference [Pa]

This field allows the user to output the pressure drop of a particular branch on a plant loop or condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop or CondenserLoop object.

### 1.20.4 ConnectorList

A connector list is a collection of either one or two connection devices ([Connector:Mixer](#) or [Connector:Splitter](#)). Due to the definition of a loop in EnergyPlus, there is a maximum of one mixer and one splitter allowed for each loop segment. This limitation still allows a tremendous amount of flexibility to the user and can also still be solved within a reasonable amount of time and without a complex solver routine. The connection list simply allows the specification of the types and names of these devices. This allows the main loop statements to have the flexibility to have multiple lists that can have one or more item.

### 1.20.4.1 Inputs

#### 1.20.4.1.1 Field: Name

This field is an identifying name that will be referenced to main loop statements using this connector list. The name must be unique among connector list names.

#### 1.20.4.1.2 Field-Set: Connection Object Type and Identifying Name (up to 2 allowed)

Depending on the loop, either one or two of the connectors will be specified. If this particular loop only has a single connector (either **Connector:Mixer** or **Connector:Splitter**), then only the first two items (type of connection and identifying name of connector) are included. If both a mixer and splitter are present, the additional type of connection and identifying name must be included. Note that the order that the items appear is inconsequential—either the **Connector:Mixer** or the **Connector:Splitter** may appear first. This will not affect the simulation.

#### 1.20.4.1.3 Field: Connector 1 Object Type

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

#### 1.20.4.1.4 Field: Connector 1 Name

This field is an identifying name for the connector. It will be used by other objects in the input file.

#### 1.20.4.1.5 Field: Connector 2 Object Type (optional)

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

#### 1.20.4.1.6 Field: Connector 2 Name (optional)

This field is an identifying name for the connector. It will be used by other objects in the input file.

An example of this statement in an IDF is:

```
ConnectorList LIST, Cooling Supply Side Connectors,
  Connector:Splitter, CW Loop Splitter,
  Connector:Mixer, CW Loop Mixer;
```

### 1.20.4.2 Outputs

No output directly related to Connector Lists is currently presented.

## 1.20.5 Plant Loop Connectors

The connector list described in the preceding subsection determines how the branches of a particular loop will be hooked together. These connections can be classified either as a separation of a single stream into several outlet streams (splitter) or the merging of several streams into a single outlet stream (mixer). Due to the limitation per branch of a single splitter and a single mixer, the connector list can only have two pieces of equipment as a maximum. The names defined for either/both the splitter or/and the mixer refer then to “component” definitions as described in the next two subsections.

The format of both the **Connector:Splitter** and **Connector:Mixer** statements is similar. Both begin with an identifying name followed by the branch name of the “single side” of the component. In the case of the splitter, this is the inlet since the inlet stream is broken into several outlet streams. In the case of the mixer, this is the outlet since several streams are mixed together to form a single outlet. The remaining list of up to 50 names is simply the branch names of the outlet legs in the case of the splitter

and inlet legs in the case of the mixer. No control logic is assume in these components—a determination of how much air to split in which direction using the splitter must be defined by other components.

## 1.20.6 Connector:Splitter

A Connector:Splitter is used to take a single fluid stream or branch and split it into more than one outlet branches. This input object is used purely to connect the inlet and outlet branches.

### 1.20.6.1 Inputs

#### 1.20.6.1.1 Field: Name

This alpha field contains the identifying name for the Splitter.

#### 1.20.6.1.2 Field: Inlet Branch Name

This alpha field contains the identifying name for the Splitter Inlet Branch.

#### 1.20.6.1.3 Field: Outlet Branch <x> Name

This alpha field contains the identifying names for the Splitter Outlet Branches and you enter as many outlet branches as needed.

## 1.20.7 Connector:Mixer

A Connector:Mixer is used to combine or mix several inlet branches into a single outlet branch. This input object is used purely to connect the inlet branches with the outlet branch.

### 1.20.7.1 Inputs

#### 1.20.7.1.1 Field: Name

This alpha field contains the identifying name for the Mixer.

#### 1.20.7.1.2 Field: Outlet Branch Name

This alpha field contains the identifying name for the Mixer Outlet Branch.

#### 1.20.7.1.3 Field: Inlet Branch <x> Name

This alpha field contains the identifying names for the Mixer Inlet Branches and you enter as many inlet branch names as needed..

An example of these statements in an IDF is:

```
Connector:Splitter,
    CW Loop Splitter,
    CW Pump Branch,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
Connector:Mixer,
    CW Loop Mixer,
    Cooling Supply Outlet,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
```

## 1.20.8 Pipe:Adiabatic

In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic component is currently used more as a connection device (for branches that really do not have any components associated with them) or as a bypass than anything else. As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component.

### 1.20.8.1 Inputs

#### 1.20.8.1.1 Field: Name

This alpha field is used as an identifying field for the pipe.

#### 1.20.8.1.2 Field: Inlet Node Name

This alpha field is used as an identifying field for the pipe inlet node.

#### 1.20.8.1.3 Field: Outlet Node Name

This alpha field is used as an identifying field for the pipe outlet node.

An example of this statement in an IDF is:

```
Pipe:Adiabatic,
  Demand Side Inlet Pipe,
  CW Demand Inlet Node,
  CW Demand Entrance Pipe Outlet Node;
```

### 1.20.8.2 Outputs

There are no outputs directly related to Pipes.

## 1.20.9 Pipe:Adiabatic:Steam

To connect the various components in a steam system regardless of it being the condensate or the steam side of the loop steam pipe needs to be used. In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic:Steam component is currently used more as a connection device (for branches that really do not have any components associated with them). As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component.

### 1.20.9.1 Inputs

#### 1.20.9.1.1 Field: Name

This alpha field is used as an identifying field for the steam pipe.

#### 1.20.9.1.2 Field: Inlet Node Name

This alpha field is used as an identifying field for the steam pipe inlet node.

### 1.20.9.1.3 Field: Outlet Node Name

This alpha field is used as an identifying field for the steampipe outlet node.

An example of this statement in an IDF is:

```
Pipe:Adiabatic:Steam,
  Steam Demand 1 Steam Inlet Pipe,           !- PipeName
  Steam Demand 1 Steam Demand Inlet Node,    !- Inlet Node Name
  Steam Demand 1 Steam Demand Entrance Pipe Outlet Node; !- Outlet Node Name
```

---

### 1.20.9.2 Outputs

There are no outputs directly related to Steam Pipes.

## 1.20.10 Pipe:Indoor

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in a zone or when a user schedule is used to specify an environment.

The data definition for object is shown below.

### 1.20.10.1 Inputs

#### 1.20.10.1.1 Field: Name

This alpha field is used as an identifying field for the pipe.

#### 1.20.10.1.2 Field: Construction Name

This alpha field references a ‘wall’ construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

#### 1.20.10.1.3 Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

#### 1.20.10.1.4 Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

#### 1.20.10.1.5 Field: Environment Type

Environment type is the environment in which the pipe is placed. It can be either **Zone** or **Schedule**. If specified as Zone, a zone name must be specified in the next field. If specified as Schedule, the Ambient Temperature Zone can be left blank, while a schedule must be specified for the temperature and air velocity.

#### 1.20.10.1.6 Field: Ambient Temperature Zone Name

If **Zone** is specified as the environment type, this field is used to specify the name of the zone in which the pipe is located. The zone temperature is used to calculate the heat transfer rate from the pipe.

#### 1.20.10.1.7 Field: Ambient Temperature Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the temperature schedule that gives the ambient air temperature surrounding the pipe. This temperature is used as the outside boundary condition to calculate heat transfer from the pipe.

#### 1.20.10.1.8 Field: Ambient Air Velocity Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the velocity schedule that gives the air velocity near the pipe. This velocity is used to calculate the convection heat transfer coefficient used in the pipe heat transfer calculation.

#### 1.20.10.1.9 Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive number.

#### 1.20.10.1.10 Field: Pipe Length

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive number.

An example of this object in an IDF is:

```
Pipe:Indoor,
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger
  Insulated Pipe,               !- Construction name
  Condenser Tower Outlet Node,  !- Comp1 Inlet Node Name
  HTPipe Outlet Node,          !- Comp1 Outlet Node Name
  Water,                        !- Fluid name
  Zone,                         !- field Ambient Temperature Outside Air Node name
  0.05,                         !- Pipe Inside Diameter (thickness in construction data)
  100.0;                        !- pipe length
```

#### 1.20.10.2 Outputs

- HVAC,Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC,Average, Pipe Ambient Heat Transfer Rate [W]
- HVAC,SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC,SUM, Pipe Ambient Heat Transfer Energy [J]
- HVAC,Average, Pipe Mass Flow Rate [kg/s]
- HVAC,Average, Pipe Inlet Temperature [C]
- HVAC,Average, Pipe Outlet Temperature [C]
- HVAC,Average, Pipe Volume Flow Rate [m<sup>3</sup>/s]

##### 1.20.10.2.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

##### 1.20.10.2.2 Pipe Ambient Heat Transfer Rate [W]

The output provides the amount of heat loss/gain from pipe wall to the environment.

##### 1.20.10.2.3 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

##### 1.20.10.2.4 Pipe Ambient Heat Transfer Energy [J]

Total energy lost from the external pipe surface.

**1.20.10.2.5 Pipe Mass Flow Rate [kg/s]**

Mass flow rate of the fluid in the pipe.

**1.20.10.2.6 Pipe Inlet Temperature [C]****1.20.10.2.7 Pipe Outlet Temperature [C]**

Temperature of fluid at entering and exiting of pipe.

**1.20.10.2.8 Pipe Volume Flow Rate [m<sup>3</sup>/s]**

Fluid volumetric flow rate, (mass flow rate / density)

**1.20.11 Pipe:Outdoor**

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in an outdoor environment.

**1.20.11.1 Inputs****1.20.11.1.1 Field: Name**

This alpha field is used as an identifying field for the pipe.

**1.20.11.1.2 Field: Construction Name**

This alpha field references a ‘wall’ construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

**1.20.11.1.3 Field: Fluid Inlet Node Name**

This alpha field contains the name of the pipe fluid inlet node.

**1.20.11.1.4 Field: Fluid Outlet Node Name**

This alpha field contains the name of the pipe fluid outlet node.

**1.20.11.1.5 Field: Ambient Temperature Outside Air Node Name**

Ambient temperature outdoor air node is a node representing outdoor air with which pipe transfers heat. The node should be included in an outdoor air node list.

**1.20.11.1.6 Field: Pipe Inside Diameter**

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

**1.20.11.1.7 Field: Pipe Length**

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive quantity. An example of this statement in an IDF is:

```
Pipe:Outdoor,
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger
  Insulated Pipe,               !- Construction name
  Condenser Tower Outlet Node, !- Comp1 Inlet Node Name
  HTPipe Outlet Node,          !- Comp1 Outlet Node Name
  Water,                      !- Fluid name
```

```

PipeHeatTransfer Inlet Node,      !- field Ambient Temperature Outside Air Node name
0.05,                         !- Pipe Inside Diameter (thickness given in construction data)
100.0;                          !- pipe length

```

---

### 1.20.11.2 Outputs

- HVAC,Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC,SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC,Average, Pipe Mass Flow Rate [kg/s]
- HVAC,Average, Pipe Inlet Temperature [T]
- HVAC,Average, Pipe Outlet Temperature [T]
- HVAC,Average, Pipe Volume Flow Rate [m<sup>3</sup>/s]

#### 1.20.11.2.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

#### 1.20.11.2.2 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

#### 1.20.11.2.3 Pipe Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

#### 1.20.11.2.4 Pipe Inlet Temperature [C]

#### 1.20.11.2.5 Pipe Outlet Temperature [C]

Temperature of fluid at entering and exiting of pipe.

#### 1.20.11.2.6 Pipe Volume Flow Rate [m<sup>3</sup>/s]

Fluid volumetric flow rate, (mass flow rate / density)

### 1.20.12 Pipe:Underground

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed underground.

#### 1.20.12.1 Inputs

##### 1.20.12.1.1 Field: Name

This alpha field is used as an identifying field for the pipe.

##### 1.20.12.1.2 Field: Construction Name

This alpha field references a basic construction object that gives a layer-by-layer description of the pipe wall and insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost layer, the insulation, if it exists, and ending with the pipe wall layer. The construction object may have either one or two layers. If only one, then the material must be the pipe wall. If two, then insulation is utilized.

#### 1.20.12.1.3 Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

#### 1.20.12.1.4 Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

#### 1.20.12.1.5 Field: Sun Exposure

This alpha field allows the user to specify one of two options: NoSun or SunExposed. For SunExposed, the simulation includes diffuse and beam solar effects on the ground surface. For NoSun, no solar effects are included.

#### 1.20.12.1.6 Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

#### 1.20.12.1.7 Field: Pipe Length

This field is used to enter the length of the pipe in units of {m}. Pipe length must be a positive quantity.

#### 1.20.12.1.8 Field: Soil Material Name

This references a **Material** object that contains the soil properties and thickness. Note that when defining the soil layer, the thickness should be the thickness of soil between the pipe wall and the ground surface.

#### 1.20.12.1.9 Field: Type of Undisturbed Ground Temperature Object

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

#### 1.20.12.1.10 Field: Name of Undisturbed Ground Temperature Object

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

An example of this object in an IDF is:

```
Pipe:Underground,
  Pipe Heat Transfer Towers,          !- Name of Pipe
  Insulated Buried Pipe,            !- Construction Name
  Condenser Tower Outlet Node,     !- Inlet Node Name
  HT Pipe Outlet Node,             !- Outlet Node Name
  Water,                           !- Fluid Name
  SunExposed,                      !- Sun Exposure
  0.05,                            !- Pipe Inside Diameter
  20.0,                            !- Pipe Length
  Buried Pipe Soil,                !- Soil Material
  Site:GroundTemperature:Undisturbed:KusudaAchenbach, !- Type of Undisturbed Ground Temperature
Object
  KATemps;                         !- Name of Undisturbed Ground Temperature Object

### 1.20.12.2 Outputs

- HVAC, Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC, SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC, Average, Pipe Mass Flow Rate [kg/s]
- HVAC, Average, Pipe Volume Flow Rate [m<sup>3</sup>/s]
- HVAC, Average, Pipe Inlet Temperature [C]
- HVAC, Average, Pipe Outlet Temperature [C]

#### 1.20.12.2.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

#### 1.20.12.2.2 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

#### 1.20.12.2.3 Pipe Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

#### 1.20.12.2.4 Pipe Volume Flow Rate [m<sup>3</sup>/s]

Fluid volumetric flow rate, (mass flow rate / density)

#### 1.20.12.2.5 Pipe Inlet Temperature [C]

#### 1.20.12.2.6 Pipe Outlet Temperature [C]

Temperature of fluid at entrance and exit of pipe.

### 1.20.13 PipingSystem:Underground Class Objects

Objects in this class are used to simulate the heat transfer processes of a piping system placed underground, which may or may not be in contact with a number of zone surfaces. There are three related objects, all of which are prefixed with PipingSystem:Underground :

- PipingSystem:Underground:Domain
- PipingSystem:Underground:PipeCircuit
- PipingSystem:Underground:PipeSegment

## 1.20.14 PipingSystem:Underground:Domain

This section documents the domain object, which is used to specify information for the overall ground domain, including thermal properties, mesh parameters, and surface interaction.

### 1.20.14.1 Inputs

#### 1.20.14.1.1 Field: Name

This alpha field is used as an identifying field for the ground domain.

#### 1.20.14.1.2 Field: XMax, YMax, ZMax

These numeric fields are used to specify the overall domain size, in each of the three Cartesian dimensions. The domain will be meshed from  $\{x, y, z\} = \{0, 0, 0\}$  to  $\{Xmax, Ymax, Zmax\}$ .

Note that for this object, the x-z plane lies parallel to the ground surface, such that the y-dimension can be thought of as representing the burial depth. This is in contrast to the way building surface coordinates are defined with the x-y plane lying parallel to the ground. Also note that any pipe segments that end up being used in a ground domain will be placed axially in the z-dimension. Thus, pipe flow will always be in either the positive z or negative z direction.

#### 1.20.14.1.3 Field: X-Direction Mesh Density Parameter

This numeric integer field represents the number of cells to be placed between any two “domain partitions” during mesh development. A domain partition may be thought of as a basement wall/floor, or a pipe. Once these components are laid out in the domain, this field number of cells are placed between the partitions. Further information on this is found in the engineering reference manual.

#### 1.20.14.1.4 Field: X-Direction Mesh Type

This alpha field represents the type of mesh to create when placing cells between “domain partitions.” Two options are available: “uniform” and “symmetricgeometric.” For uniform, the cells are placed in the region with all cells having equal size. For symmetric-geometric, the cells are compressed toward the partitions so that there are more cells on either side of the mesh region. This can help focus computational intensity on the boundary areas where it is likely more desired. For symmetric-geometric mesh distribution, the mesh density parameter should be an even number to provide the symmetric condition.

#### 1.20.14.1.5 Field: X-Direction Geometric Coefficient

This numeric field represents the compression of cell distribution if the x-direction mesh type is set to “symmetricgeometric.” If the mesh type is uniform, this field is not interpreted. For symmetric geometric, a value in this field equal to 1 would result in a uniform distribution, while a value of 2 would provide a highly skewed distribution.

#### 1.20.14.1.6 Field: Y-Direction Mesh Density Parameter

See Field: X-Direction Mesh Density Parameter.

#### 1.20.14.1.7 Field: Y-Direction Mesh Type

See Field: X-Direction Mesh Type.

#### 1.20.14.1.8 Field: Y-Direction Geometric Coefficient

See Field: X-Direction Geometric Coefficient.

**1.20.14.1.9 Field: Z-Direction Mesh Density Parameter**

See Field: X-Direction Mesh Density Parameter.

**1.20.14.1.10 Field: Z-Direction Mesh Type**

See Field: X-Direction Mesh Type.

**1.20.14.1.11 Field: Z-Direction Geometric Coefficient**

See Field: X-Direction Geometric Coefficient.

**1.20.14.1.12 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

**1.20.14.1.13 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

**1.20.14.1.14 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

**1.20.14.1.15 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

**1.20.14.1.16 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil

**1.20.14.1.17 Field: Type of Undisturbed Ground Temperature Object**

The type of undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.20.14.1.18 Field: Name of Undisturbed Ground Temperature Object**

The name of the undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.20.14.1.19 Field: This Domain Includes Basement Surface Interaction**

A yes/no field stating whether zone surfaces should be coupled to this domain.

**1.20.14.1.20 Field: Width of Basement Floor in Ground Domain**

If this domain does include basement interaction, this represents the width of the domain cutaway to include the basement. In essence, this is the width of basement floor to include in the ground simulation. This width should *include* the basement wall thickness.

**1.20.14.1.21 Field: Depth of Basement Floor in Ground Domain**

If this domain does include basement interaction, this represents the depth of the domain cutaway to include the basement. In essence, this is the burial depth of the basement to include in the ground simulation. This depth should include the basement floor thickness.

**1.20.14.1.22 Field: Shift Pipe X Coordinates By Basement Width**

If this domain does include basement interaction, this flag specifies whether the pipe segment X-values should then be shifted by the basement width. In essence, this specifies the reference point for pipe segment x-values: if NO then the reference is domain  $x = 0$ , if YES then the reference is the basement width point.

**1.20.14.1.23 Field: Name of Basement Wall Boundary Condition Model**

The name of an OtherSideConditions model defined in the input file and referenced by the surfaces which should be included as “wall surfaces” for the basement interaction part of the ground heat transfer model.

**1.20.14.1.24 Field: Name of Basement Wall Boundary Condition Model**

The name of an OtherSideConditions model defined in the input file and referenced by the surfaces which should be included as “floor surfaces” for the basement interaction part of the ground heat transfer model.

**1.20.14.1.25 Field: Convergence Criterion for the Outer Cartesian Domain Iteration Loop**

The maximum temperature deviation within any cell between one iteration and another to decide that the Cartesian domain has converged to within tolerance. A smaller value will improve accuracy and computation time. A smaller value should be accompanied by a higher number of iterations if maximum accuracy is desired.

**1.20.14.1.26 Field: Maximum Iterations in the Outer Cartesian Domain Iteration Loop**

The maximum number of iterations to make when performing temperature updates of the Cartesian coordinate system. The actual number of iterations made will of course depend on transient conditions and convergence tolerance.

**1.20.14.1.27 Field: Evapotranspiration Ground Cover Parameter**

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, nonpermeable ground surface) to 1.5 (wild growth).

**1.20.14.1.28 Field: Number of Pipe Circuits Entered for this Domain**

The number of pipe circuit objects which will be defined in the following fields.

**1.20.14.1.29 Field: Pipe Circuit <#>**

A **PipingSystem:Underground:PipeCircuit** to be included in this domain. This indicates that the pipe circuit and all of the underlying pipe segments will be included during mesh development and heat transfer calculations within this domain. This object is extensible, so any number of pipe circuits can be added, assuming all underlying pipe segments do not cause any conflicts for the mesh development engine (overlapping pipes, etc.).

**1.20.15 PipingSystem:Underground:PipeCircuit**

This section documents the pipe circuit object, which is used to specify information for the plant loop topology, such as inlet and outlet connections. This object also groups together pipe segments to define flow paths within a given pipe circuit.

**1.20.15.1 Inputs****1.20.15.1.1 Field: Name**

This alpha field is used as an identifying field for the pipe circuit.

**1.20.15.1.2 Field: Pipe Thermal Conductivity**

The thermal conductivity of the pipe, in W/m-K.

**1.20.15.1.3 Field: Pipe Density**

The bulk density of the pipe, in kg/m<sup>3</sup>.

**1.20.15.1.4 Field: Pipe Specific Heat**

The specific heat of the pipe, in J/kg-K.

**1.20.15.1.5 Field: Pipe Inner Diameter**

The inner diameter of the pipe, in m.

**1.20.15.1.6 Field: Pipe Outer Diameter**

The outer diameter of the pipe, in m.

**1.20.15.1.7 Field: Design Flow Rate**

The “design” flow in this pipe circuit, in m<sup>3</sup>/s. This is the flow which this component will request during the simulation. Of course, other components and overall plant management will decide the flow actually given to this component.

**1.20.15.1.8 Field: Circuit Inlet Node Name**

The inlet node name for this circuit, which is used when placing this circuit on a branch on a plant or condenser loop.

**1.20.15.1.9 Field: Circuit Outlet Node Name**

The outlet node name for this circuit, which is used when placing this circuit on a branch on a plant or condenser loop.

**1.20.15.1.10 Field: Convergence Criterion for the Inner Radial Iteration Loop**

The maximum temperature deviation within any cell between one iteration and another to decide that the radial domain has converged to within tolerance. A smaller value will improve accuracy and computation time. A smaller value should be accompanied by a higher number of iterations if maximum accuracy is desired.

**1.20.15.1.11 Field: Maximum Iterations in the Inner Radial Iteration Loop**

The maximum number of iterations to make when performing temperature updates of the radial coordinate system. The actual number of iterations made will of course depend on transient conditions and convergence tolerance.

**1.20.15.1.12 Field: Number of Soil Nodes in the Inner Radial Near Pipe Mesh Region**

The number of soil nodes to discretize pipe cells. More information on mesh development is provided in the engineering reference manual.

### 1.20.15.1.13 Field: Radial Thickness of Inner Radial Near Pipe Mesh Region

The radial distance used to discretize pipe cells. More information on mesh development is provided in the engineering reference manual.

### 1.20.15.1.14 Field: Number of Pipe Segments Entered for this Pipe Circuit

The number of pipe segment objects which will be defined in the following fields.

### 1.20.15.1.15 Field: Pipe Segment <#>

A **PipingSystem:Underground:PipeSegment** to be included in this pipe circuit. The circuit is set up so that flow passes through the  $N$  segments in the order they are entered here. This object is extensible, so additional fields of this type can be added to the end of this object.

## 1.20.16 PipingSystem:Underground:PipeSegment

This section documents the pipe segment object, which is used to specify information for a single pipe segment placed at some x, y coordinate in the ground. The flow direction is also defined in this object to allow for careful description of varying flow paths. This can be useful for accounting for short circuiting effects if two pipes are placed in counterflow vs. parallel flow.

### 1.20.16.1 Inputs

#### 1.20.16.1.1 Field: Name

This alpha field is used as an identifying field for the pipe segment.

#### 1.20.16.1.2 Field: X Position

This numeric field represents the x-direction placement of the pipe. If no basement is included in the simulation, this is measured from  $x = 0$ . If a basement is included, and the domain object specifies that pipes should be shifted, this is measured from the basement wall.

#### 1.20.16.1.3 Field: Y Position

This numeric field represents the burial depth of the pipe, measured from the ground surface. This will always be a positive number.

#### 1.20.16.1.4 Field: Flow Direction

This alpha field is used to define the flow direction within this pipe segment. The choices are “increasing” or “decreasing.” These can be chosen carefully to encapsulate specific short-circuiting effects due to varying flow configurations (circuiting).

An example of this object in an IDF is offered here for a foundation heat exchanger

- HVAC, Average, Pipe Segment Outlet Temperature [C]
- HVAC, Average, Pipe Circuit Fluid Heat Transfer Rate [W]
- HVAC, Average, Pipe Segment Fluid Heat Transfer Rate [W]

#### 1.20.16.2.1 Pipe Circuit Mass Flow Rate [kg/s]

The output provides the mass flow rate currently being sent through the pipe circuit.

#### 1.20.16.2.2 Pipe Circuit Inlet Temperature [C]

#### 1.20.16.2.3 Pipe Circuit Outlet Temperature [C]

Temperature of fluid at the inlet and outlet of a given pipe circuit.

#### 1.20.16.2.4 Pipe Segment Inlet Temperature [C]

#### 1.20.16.2.5 Pipe Segment Outlet Temperature [C]

Temperature of fluid at the inlet and outlet of a given pipe segment.

#### 1.20.16.2.6 Pipe Circuit Fluid Heat Transfer Rate [W]

This is the fluid heat gain or loss in the pipe circuit, in Watts.

#### 1.20.16.2.7 Pipe Segment Fluid Heat Transfer Rate [W]

This is the fluid heat gain or loss in the pipe segment, in Watts.

### 1.20.17 Duct

The Duct object is a component for air systems that is a direct analogue for [Pipe:Adiabatic](#) in the fluid loops. It is used when it is necessary (due to the HVAC system configuration) to have a branch that has no functional components. This case most often arises for a bypass branch. Since every branch must have at least one component, the Duct component is used for this situation. The duct is an adiabatic, pass-through component; all of its inlet conditions are passed through unchanged to its outlet.

### 1.20.17.1 Inputs

#### 1.20.17.1.1 Field: Name

This is the unique name for this component. Any reference to this component (in a **BranchList**, for instance) will refer to it by this name.

#### 1.20.17.1.2 Field: Inlet Node Name

The name of the component's air inlet node.

#### 1.20.17.1.3 Field: Outlet Node Name

The name of the component's air outlet node.

Below is an example input for Duct.

```
DUCT,
  VAV Sys 1 Bypass Duct,           !- Name
  VAV Sys 1 Bypass Duct Inlet Node, !- Inlet Node Name
  VAV Sys 1 Bypass Duct Outlet Node; !- Outlet Node Name
```

### 1.20.17.2 Outputs

There are no outputs for Duct.

## 1.21 Group – Plant-Condenser Loops

### 1.21.1 PlantLoop

The main elements of the PlantLoop syntax are described in further detail below. A map of how the input for this portion of the HVAC input fits together is provided in the following diagram.

#### 1.21.1.1 Inputs

##### 1.21.1.1.1 Field: Name

This alpha field is used as an identifying field for the plant loop.

##### 1.21.1.1.2 Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Either **Water**, **Steam** or **UserDefinedFluidType** may be used. If the UserDefinedFluidType keyword is used, the following input field i.e. User Defined Fluid Type must have a value (namely the name of a **FluidProperties:GlycolConcentration** object).

##### 1.21.1.1.3 Field: User Defined Fluid Type

This alpha field must be specified when the previous field is set to **UserDefinedFluidType** otherwise it could be left blank. **Water**, **EthyleneGlycol**, **PropyleneGlycol** and **Steam** are all “built-in” fluids for EnergyPlus (that is, all of the appropriate properties are contained within the program). If the fluid specified here is a mixture of water and ethylene or propylene glycol, then only **FluidProperties:GlycolConcentration** objects need to be specified and the name of the appropriate one is used here. For another water/glycol mixture, a complete set of fluid property data (**FluidProperties:Name** and **FluidProperties:Temperature** objects plus multiple **FluidProperties:Concentration** objects for specific heat, density, etc.) must be specified (Ref dataset: GlycolPropertiesRefData.idf).

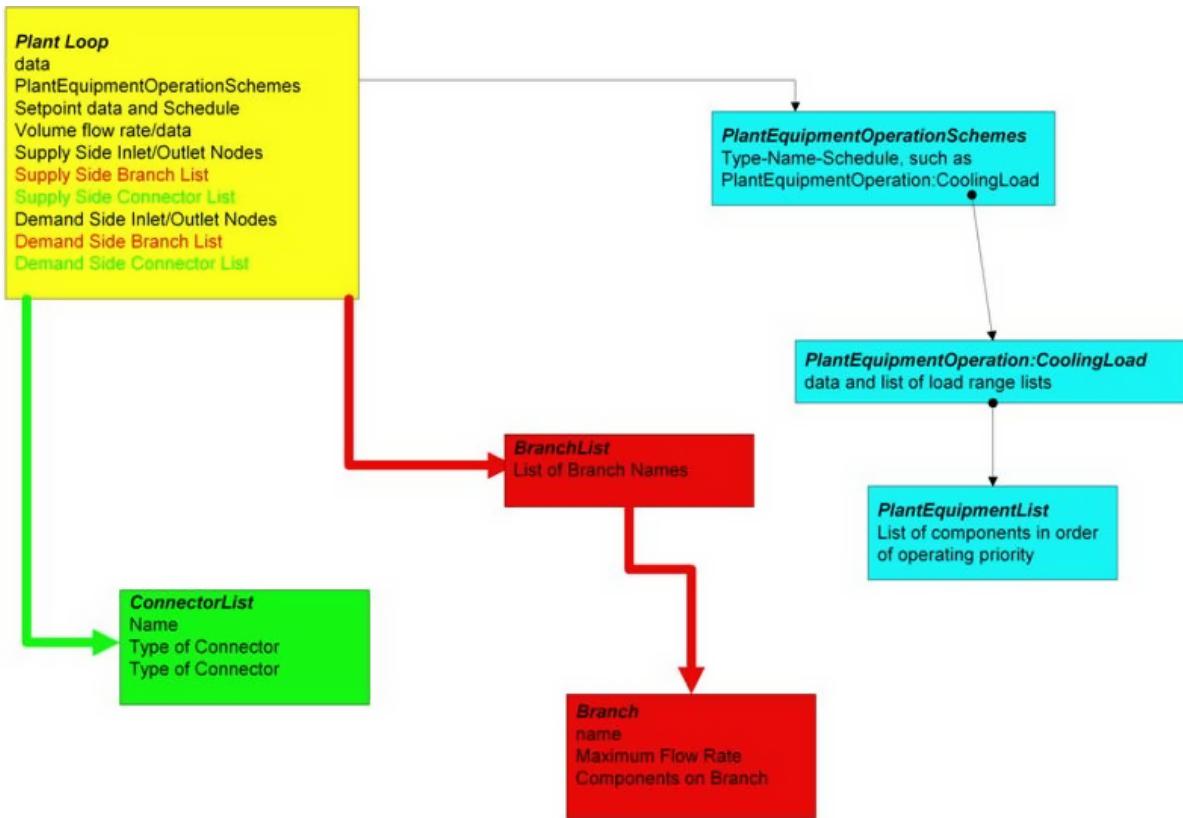

Figure 1.90: Plant Loop Input Syntax Map

#### 1.21.1.1.4 Field: Plant Equipment Operation Scheme Name

This alpha field is used as an identifying field for the plant operation scheme. This field ties to the **PlantEquipmentOperationSchemes** input structure, which must also be defined.

#### 1.21.1.1.5 Field: Loop Temperature Setpoint Node Name

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Plant Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

#### 1.21.1.1.6 Field: Maximum Loop Temperature

This numeric field contains the maximum allowable temperature in Celsius for this loop.

#### 1.21.1.1.7 Field: Minimum Loop Temperature

This numeric field contains the minimum allowable temperature in Celsius for this loop.

#### 1.21.1.1.8 Field: Maximum Loop Flow Rate

This numeric field contains the maximum loop flow rate in cubic meters per second. This parameter is also used when the user chooses to autocalculate the loop volume. See Volume of the Plant Loop below and the Engineering Manual for more details. This field is autosizable.

#### 1.21.1.1.9 Field: Minimum Loop Flow Rate

This numeric field contains the minimum loop flow rate in cubic meters per second.

#### 1.21.1.1.10 Field: Plant Loop Volume

Volume of the plant loop in m<sup>3</sup>. This numeric field contains the loop volume for the entire loop, i.e. both the demand side and the supply side. This is used for the loop capacitance calculation. Loop volume (m<sup>3</sup>) could be calculated from pipe size data but this is not usually known. If zero volume is specified the loop has no fluid heat capacity. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The **autocalculate** option sets the loop volume to the product of the Maximum Loop Flow Rate and the user input for Loop Circulation Time which defaults to 2 minutes (see below). This calculation is described in the Engineering Reference manual.

#### 1.21.1.1.11 Field: Plant Side Inlet Node Name

This required alpha field contains the identifying name given to the Plant Side Inlet Node. This node is the inlet to the supply side of the loop.

#### 1.21.1.1.12 Field: Plant Side Outlet Node Name

This required alpha field contains the identifying name given to the Plant Side Outlet Node. This node is the outlet of the supply side of the loop.

#### 1.21.1.1.13 Field: Plant Side Branch List Name

This required alpha field contains the identifying name given to the Plant Side Branch List. The list referenced here should list all the branches on the supply side of the loop.

#### 1.21.1.1.14 Field: Plant Side Connector List Name

This alpha field contains the identifying name given to the Plant Side Connector List. The list referenced here should list the splitter and mixer on the supply side of the loop.

#### 1.21.1.1.15 Field: Demand Side Inlet Node Name

This required alpha field contains the identifying name given to the Demand Side Inlet Node. This node is the inlet to the demand side of the loop.

#### 1.21.1.1.16 Field: Demand Side Outlet Node Name

This required alpha field contains the identifying name given to the Demand Side Outlet Node. This node is the outlet of the demand side of the loop.

#### 1.21.1.1.17 Field: Demand Side Branch List Name

This required alpha field contains the identifying name given to the Demand Side Branch List. The list referenced here should list all the branches on the demand side of the loop.

#### 1.21.1.1.18 Field: Demand Side Connector List Name

This alpha field contains the identifying name given to the Demand Side Connector List. The list referenced here should list the splitter and mixer on the demand side of the loop.

#### 1.21.1.1.19 Field: Load Distribution Scheme

The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional:

- **Optimal** operates each piece of equipment at its optimal part load ratio. Any remaining loop demand is distributed evenly to all of the components.

- **SequentialLoad** loads each piece of equipment sequentially in the order specified in the **PlantEquipmentList** to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand.
- **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. If some components do not have the capacity to meet the uniformly distributed load, the remaining load is distributed sequentially to the other available components.
- **SequentialUniformPLR** loads all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the **PlantEquipmentList** until each component is fully loaded, at which point the next subsequent component is added and the load is distributed uniformly based on PLR between the components.
- **UniformPLR** will load all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the **PlantEquipmentList** operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

#### 1.21.1.1.20 Field: Availability Manager List Name

This alpha field contains the identifying name given to the System Availability Manager List.

#### 1.21.1.1.21 Field: Plant Loop Demand Calculation Scheme

There are two choices for plant loop demand calculations schemes in EnergyPlus: SingleSetpoint and DualSetpointDeadband.

SingleSetpoint - For the SingleSetpoint scheme, the plant loop is controlled to a single temperature setpoint. This requires a setpoint manager with Control Variable = Temperature to place a setpoint on the Loop Temperature Setpoint Node. The setpoint will be stored in the **Node%TempSetpoint** variable which may be reported using **Output:Variable** "System Node Setpoint Temperature." Examples of applicable setpoint managers include: **SetpointManager:Scheduled**, **SetpointManager:OutdoorAirReset**, **SetpointManager:FollowOutdoorAirTemperature**, etc. SingleSetpoint is the default.

DualSetpoint - For the DualSetpoint scheme, the plant loop is controlled to stay between a pair of high and low temperature setpoints. This requires one or two setpoint managers to place two setpoints on the Loop Temperature Setpoint Node. The setpoints will be stored in the **Node%TempSetPointHi** and **Node%TempSetPointLo** variables which may be reported using **Output:Variable** "System Node Setpoint High Temperature" and "System Node Setpoint Low Temperature." There is special setpoint manager, **SetpointManager:Scheduled:DualSetpoint**, which will place both the high and low setpoints with Control Variable = Temperature. Otherwise, two setpoint managers are required, one with Control Variable = MaximumTemperature and another with Control Variable = MinimumTemperature. The two setpoint managers may be the same kind or different, but care should be taken so that the MinimumTemperature is not set higher than the MaximumTemperature. Examples of applicable setpoint managers include: **SetpointManager:Scheduled**, **SetpointManager:OutdoorAirReset**, **SetpointManager:FollowOutdoorAirTemperature**, etc. Note that DualSetpoint is used only for plant loops with both heating and cooling supply equipment, such as a water loop heat pump system. When the loop temperature rises above the MaximumTemperature setpoint, then the loop will request cooling, and when the loop temperature is below the MinimumTemperature setpoint it will request heating. DualSetpoint

cannot be used to control a single-mode loop, such as a hot water heating loop between operating between high and low boiler setpoints.

The plant loop demand calculation scheme determines the amount of heating or cooling necessary to bring the temperature of the Plant Loop to its setpoint(s). When this value is determined then the load distribution scheme explained in the previous section takes this value and distributes the load to the appropriate equipment. The demand calculation scheme determines how the load is calculated. See more information in the Engineering Document.

#### **1.21.1.1.22 Field: Common Pipe Simulation**

This field specifies a primary-secondary plant loop simulation. When a common pipe option is specified, the plant side of the loop is the primary loop and the demand side of the loop is the secondary loop, and a pump object must be placed on the demand side inlet branch. The three options are “**None**”, “**CommonPipe**” and “**TwoWayCommonPipe**”. “**None**” means that there is no secondary loop and the plant loop is modeled as a single primary loop. “**CommonPipe**” means that the common pipe interface does not attempt any temperature control, it only satisfies secondary (demand side) flow requests. “**TwoWayCommonPipe**” allows control of the secondary (demand side) inlet temperature or the primary (plant side) inlet temperature by placing a setpoint on the corresponding node. If this field is left blank, it will default to “**None**”. If the field is set to “**None**” and the program finds a pump on the demand side it will result in a fatal error. If the field is set to “**CommonPipe**” or “**TwoWayCommonPipe**” and the program does not find a pump on the demand side it will result in a fatal error. The common pipe simulation is currently limited to simulating loop pumps, i.e. each pump should be placed on the inlet branch of the plant side or demand side of the loop.

#### **1.21.1.1.23 Field: Pressure Simulation Type**

This field lets user to choose if this plant loop will be involved in a pressure drop calculation. This requires that at least one branch on the loop have pressure drop data. If not, an error will be thrown due to the input mismatch. Currently there are two pressure drop simulation types: “**PumpPowerCorrection**” and “**LoopFlowCorrection**”. In both of these methods, branch pressure drop data is used to calculate a dynamic loop pressure drop and is used to update pumping power accordingly. The flow correction method allows the user to enter information regarding the pressure curve of a constant speed pump so that the simulation can dynamically resolve the pressure vs. flow relationship in the plant loop. This is limited to constant speed pumps, as the variable speed pumps are expected to resolve as if it were controlled by a variable drive, so that they can inherently meet any pressure and flow demand required by the loop. This is also limited to “loop pumps”, where there is a single pump on the plant loop. Common pipe simulations and “branch pump” simulations are not compatible with this level of pressure simulation. See the documentation for the **Pump:ConstantSpeed** in order to determine required inputs for this pressure simulation method to be performed. In the pressure drop system, parallel flow rates are not resolved (to match the pressure drop for the parallel system). Enhancements to this calculation are planned which will allow parallel branch flow resolution. See the Engineering Reference document for more information on how this works.

#### **1.21.1.1.24 Field: Loop Circulation Time**

This field specifies the time it takes the fluid to circulate through the entire loop. It is only used when Plant Loop Volume is set to autocalculate. The default is 2 minutes.

An example of this statement used in an IDF is:

```
PlantLoop,
  Hot Water Loop,           !- Plant Loop Name
  Water,                   !- Fluid Type
  ,                        !- User Defined Fluid Type
```

```

Hot Loop Operation,      !- Plant Operation Scheme List Name
HW Loop Outlet Node,   !- Loop Temperature Setpoint Schedule Name
100,                   !- Maximum Loop Temperature {C}
10,                    !- Minimum Loop Temperature {C}
autosize,              !- Maximum Loop Volumetric Flow Rate {m3/s}
0.0,                   !- Minimum Loop Volumetric Flow Rate {m3/s}
autosize,              !- volume of the plant loop {m3}
HW Supply Inlet Node,  !- Plant Side Inlet Node Name
HW Supply Outlet Node, !- Plant Side Outlet Node Name
Heating Supply Side Branches, !- Plant Side Branch List Name
Heating Supply Side Connectors, !- Plant Side Connector List Name
HW Demand Inlet Node,   !- Demand Side Inlet Node Name
HW Demand Outlet Node, !- Demand Side Outlet Nodes Name
Heating Demand Side Branches, !- Demand Side Branch List Name
Heating Demand Side Connectors, !- Demand Side Connector List Name
Optimal;               !- Load Distribution Scheme

```

In the above example input there is no system availability manager specified and the Demand Calculation Scheme will default to SingleSetpoint using a single setpoint manager. Common pipe simulation field in the above example will default to “NONE” since it is not specified.

### 1.21.1.2 Outputs

In the following output variables, “Debug” denotes variables that are used primarily by the developers and whose names and application may be cryptic to users. .

- HVAC,Average,Plant Supply Side Cooling Demand Rate [W]
- HVAC,Average,Plant Supply Side Heating Demand Rate [W]
- HVAC,Average,Plant Supply Side Inlet Mass Flow Rate [kg/s]
- HVAC,Average,Plant Supply Side Inlet Temperature [C]
- HVAC,Average,Plant Supply Side Outlet Temperature [C]
- HVAC,Average,Plant Supply Side Not Distributed Demand Rate [W]
- HVAC,Average,Plant Supply Side Unmet Demand Rate [W]
- HVAC,Sum,Plant Solver Sub Iteration Count []
- HVAC,Sum,Plant Solver Half Loop Calls Count []
- HVAC,Average,Debug Plant Loop Bypass Fraction
- HVAC,Average,Debug Plant Last Simulated Loop Side [-]
- HVAC,Average,Plant Common Pipe Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Temperature [C]
- HVAC,Average,Plant Common Pipe Flow Direction Status []
- HVAC,Average,Plant Common Pipe Primary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Secondary Mass Flow Rate [Kg/s]
- HVAC,Average,Primary Side Common Pipe Flow Direction []

- HVAC,Average,Secondary Side Common Pipe Flow Direction []
- HVAC,Average,Plant Common Pipe Primary to Secondary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Secondary to Primary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant System Cycle On Off Status []
- HVAC,Average,Plant Demand Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Supply Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Loop Pressure Difference [Pa]

#### **1.21.1.2.1 Plant Supply Side Cooling Demand Rate [W]**

This is the value of the net demand required to meet the cooling setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Cooling Demand Rate will equal sum of the total cooling demand from the demand side coils on the loop. It will also equal the cooling output of all chillers (or other cooling equipment) on the loop less any pump heat added to the fluid. For example, for a chilled water loop with one chiller and one pump serving one chilled water coil: Plant Supply Side Cooling Demand Rate will equal the chiller evaporator heat transfer less the pump heat to fluid, and it will also equal the chilled water coil total cooling output.

If the plant loop setpoint is not met, Plant Supply Side Cooling Demand Rate will equal the sum of the total cooling demand from the demand side coils on the loop plus the additional cooling required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Cooling Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### **1.21.1.2.2 Plant Supply Side Heating Demand Rate [W]**

This is the value of the net demand required to meet the heating setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Heating Demand Rate will equal sum of the total heating demand from the demand side coils on the loop. It will also equal the heating output of all boilers (or other heating equipment) on the loop plus any pump heat added to the fluid. For example, for a hot water loop with one boiler and one pump serving one hot water coil: Plant Supply Side Heating Demand Rate will equal the boiler heat transfer plus the pump heat to fluid, and it will also equal the hot water coil total heating output.

If the plant loop setpoint is not met, Plant Supply Side Heating Demand Rate will equal the sum of the total heating demand from the demand side coils on the loop plus the additional heating required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Heating Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### **1.21.1.2.3 Plant Supply Side Inlet Mass Flow Rate [kg/s]**

This is the value of the mass flow rate at the Inlet to Plant Loop on the supply side. There is not an associated Plant Loop outlet node flow rate since continuity must be maintained in the loop and the outlet must be the same.

#### **1.21.1.2.4 Plant Supply Side Inlet Temperature [C]**

This is the value of the temperature at the Inlet to the plant loop on the supply side.

**1.21.1.2.5 Plant Supply Side Outlet Temperature [C]**

This is the value of the temperature at the outlet to the plant loop on the supply side.

**1.21.1.2.6 Plant Supply Side Not Distributed Demand Rate [W]**

This is the value of the demand that could not be distributed to the plant equipment because of some constraint in the plant operation scheme. This is a record of the loop operation scheme supervisory controls after attempting to distribute the load. For example it would be non-zero in situations where the load is larger than the upper limit of capacities set for the plant equipment controls. This output is for *before* the equipment has actually been simulated whereas the separate output Plant Supply Side Unmet Demand Rate is for *after* the equipment has simulated.

**1.21.1.2.7 Plant Supply Side Unmet Demand Rate [W]**

This is the value of the demand NOT provided by the plant equipment to meet the heating or cooling setpoint of the loop. The value is positive when the plant equipment cannot meet the setpoint, and the value is negative when the plant equipment provides more than enough heating or cooling to meet the setpoint. A negative value can happen when the amount of demand is smaller than the minimum capacity of the equipment using the minimum part load ratio.

**1.21.1.2.8 Plant Solver Sub Iteration Count []**

This is the count of iterations that the overall plant simulation used over the period of time being reported. This high-level output is from the plant solver used for all the plant loops and condenser loops in the model.

**1.21.1.2.9 Plant Solver Half Loop Calls Count**

This is the count of calls to model individual half-loops that occurred during the overall plant simulation over the period of time being reported. This includes all the half-loops for both plant loops and condenser loops.

**1.21.1.2.10 Plant Common Pipe Mass Flow Rate [Kg/s]**

This output gives the magnitude of the flow through common pipe. The value is averaged over the reporting interval.

**1.21.1.2.11 Plant Common Pipe Temperature [C]**

This output gives the value of the temperature of the fluid flowing through common pipe. This value is averaged over the reporting interval.

**1.21.1.2.12 Plant Common Pipe Flow Direction Status []**

This output gives the direction of flow in common pipe. The value is an integer and can be 0, 1 or 2. Since the output value is averaged over reporting interval, a non-integer value may be shown as an output when the reporting interval is not detailed. An output value of 0 means that there was no flow in common pipe. An output value of 1 means that the secondary flow is greater than primary flow, whereas a value of 2 means that primary flow is greater than secondary flow.

**1.21.1.2.13 Plant Common Pipe Primary Mass Flow Rate [Kg/s]**

This output variable gives the mass flow in the primary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### 1.21.1.2.14 Plant Common Pipe Secondary Mass Flow Rate [Kg/s]

This output variable gives the mass flow in the secondary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### 1.21.1.2.15 Primary Side Common Pipe Flow Direction []

This output variable gives the direction of flow in a primary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for primary side, a value of 1 means the flow is from Primary side inlet to Primary side outlet and a value of 2 means flow is from Primary side outlet to Primary side inlet.

#### 1.21.1.2.16 Secondary Side Common Pipe Flow Direction []

This output variable gives the direction of flow in a Secondary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for Secondary side, a value of 1 means the flow is from Secondary side outlet to Secondary side inlet and a value of 2 means flow is from Secondary side inlet to Secondary side outlet. Note that this is opposite to the primary side common pipe.

#### 1.21.1.2.17 Plant Common Pipe Primary to Secondary Mass Flow Rate [Kg/s]

This output variable gives the mass flow from primary to secondary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### 1.21.1.2.18 Plant Common Pipe Secondary to Primary Mass Flow Rate [Kg/s]

This output variable gives the mass flow from secondary to primary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### 1.21.1.2.19 Plant System Cycle On Off Status

This field is the availability status of a Plant Loop. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determined by the rules associated with Plant Loops (see rules described for Group – System Availability Managers). The control status outputs are represented using integers 0 through 2.. These integers represent *NoAction* (0), *ForceOff* (1), and *CycleOn* (2). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

#### 1.21.1.2.20 Plant Demand Side Loop Pressure Difference [Pa]

This field allows the user to output the demand side pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is only relevant if the user puts that curve on the demand side of the loop.

### **1.21.1.2.21 Plant Supply Side Loop Pressure Difference [Pa]**

This field allows the user to output the supply side pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is only relevant if the user puts that curve on the supply side of the loop.

### **1.21.1.2.22 Plant Loop Pressure Difference [Pa]**

This output is the total pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is relevant regardless of the location of pressure drop curves: demand side, supply side, or both.

The following advanced output variables are also available for plant loops (and condenser loops) when advanced output variables are requested (e.g. “Output:Diagnostics, DisplayAdvancedReportVariable;”).

- HVAC,Average,Plant Demand Side Lumped Capacitance Temperature [C]
- HVAC,Average,Plant Supply Side Lumped Capacitance Temperature [C]
- HVAC,Average,Plant Demand Side Lumped Capacitance Heat Transport Rate [W]
- HVAC,Average,Plant Supply Side Lumped Capacitance Heat Transport Rate [W]
- HVAC,Average,Plant Demand Side Lumped Capacitance Heat Storage Rate [W]
- HVAC,Average,Plant Supply Side Lumped Capacitance Heat Storage Rate [W]
- HVAC,Sum,Plant Demand Side Lumped Capacitance Excessive Storage Time [hr]
- HVAC,Sum,Plant Supply Side Lumped Capacitance Excessive Storage Time [hrW]
- HVAC,Average,Plant Component Distributed Demand Rate [W]

### **1.21.1.2.23 Plant Demand Side Lumped Capacitance Temperature [C]**

### **1.21.1.2.24 Plant Supply Side Lumped Capacitance Temperature [C]**

These two outputs are the temperature of the plant (or condenser) loop’s working fluid where the two half-loops interface together. The program models heat capacitance in the volume of fluid inside the plant loop itself using two simple models for “well-stirred” tanks located at each of the half-loop inlet and outlet pairs. These tank models also receive the heat transferred to the fluid by the work done by pumping and resulting friction heating. One output is for the point where the fluid leaves the supply side and enters the demand side. The other output is for the point where the fluid leaves the demand side and enters the supply side.

### **1.21.1.2.25 Plant Demand Side Lumped Capacitance Heat Transport Rate [C]**

### 1.21.1.2.26 Plant Supply Side Lumped Capacitance Heat Transport Rate [C]

These two outputs are the heat transfer rate to the plant (or condenser) loop's working fluid in the two half-loops. The program models heat capacitance in the volume of fluid inside the plant loop itself using two simple models for *well-stirred* tanks located at each of the half-loop inlet and outlet pairs. These tank models also receive the heat transferred to the fluid by the work done by pumping and resulting friction heating. One output is for the point where the fluid leaves the supply side and enters the demand side. The other output is for the point where the fluid leaves the demand side and enters the supply side.

### 1.21.1.2.27 Plant Demand Side Lumped Capacitance Heat Storage Rate [C]

### 1.21.1.2.28 Plant Supply Side Lumped Capacitance Heat Storage Rate [C]

These two outputs are the heat storage rate of the plant (or condenser) loop's working fluid in the two half-loops. The program models heat capacitance in the volume of fluid inside the plant loop itself using two simple models for *well-stirred* tanks located at each of the half-loop inlet and outlet pairs. These tank models also receive the heat transferred to the fluid by the work done by pumping and resulting friction heating. One output is for the point where the fluid leaves the supply side and enters the demand side. The other output is for the point where the fluid leaves the demand side and enters the supply side.

### 1.21.1.2.29 Plant Demand Side Lumped Capacitance Excessive Storage Time [C]

### 1.21.1.2.30 Plant Supply Side Lumped Capacitance Excessive Storage Time [C]

These two outputs are the excess storage time of the plant (or condenser) loop's working fluid in the two half-loops. The excess storage time is determined by adding the time when the heat storage rate exceeds the heat transfer rate into the two half-loops at each time step. The program models heat capacitance in the volume of fluid inside the plant loop itself using two simple models for *well-stirred* tanks located at each of the half-loop inlet and outlet pairs. These tank models also receive the heat transferred to the fluid by the work done by pumping and resulting friction heating. One output is for the point where the fluid leaves the supply side and enters the demand side. The other output is for the point where the fluid leaves the demand side and enters the supply side.

### 1.21.1.2.31 Plant Component Distributed Demand Rate [W]

This output is available for every component on every branch in a plant (or condenser) loop and shows the outcome of the load dispatch performed by the operation schemes. This is the load in watts passed from the supervisor routines to the equipment component models. This provides a record of what a particular component was asked to do by the supervisory routines. This can be useful for diagnosing issues in operation schemes when a component or loop is failing to meet the load.

## 1.21.2 CondenserLoop

The condenser loop input is very similar to that for the plant loop. As of version 7, the two loops are modeled the same way and inside the program all condenser loops are just plant loops. (In future versions of the program, this CondenserLoop object might be deprecated and these loops will be described using the [PlantLoop](#) object.) The main differences are the applicable components and operation schemes. This is depicted in the following diagram.

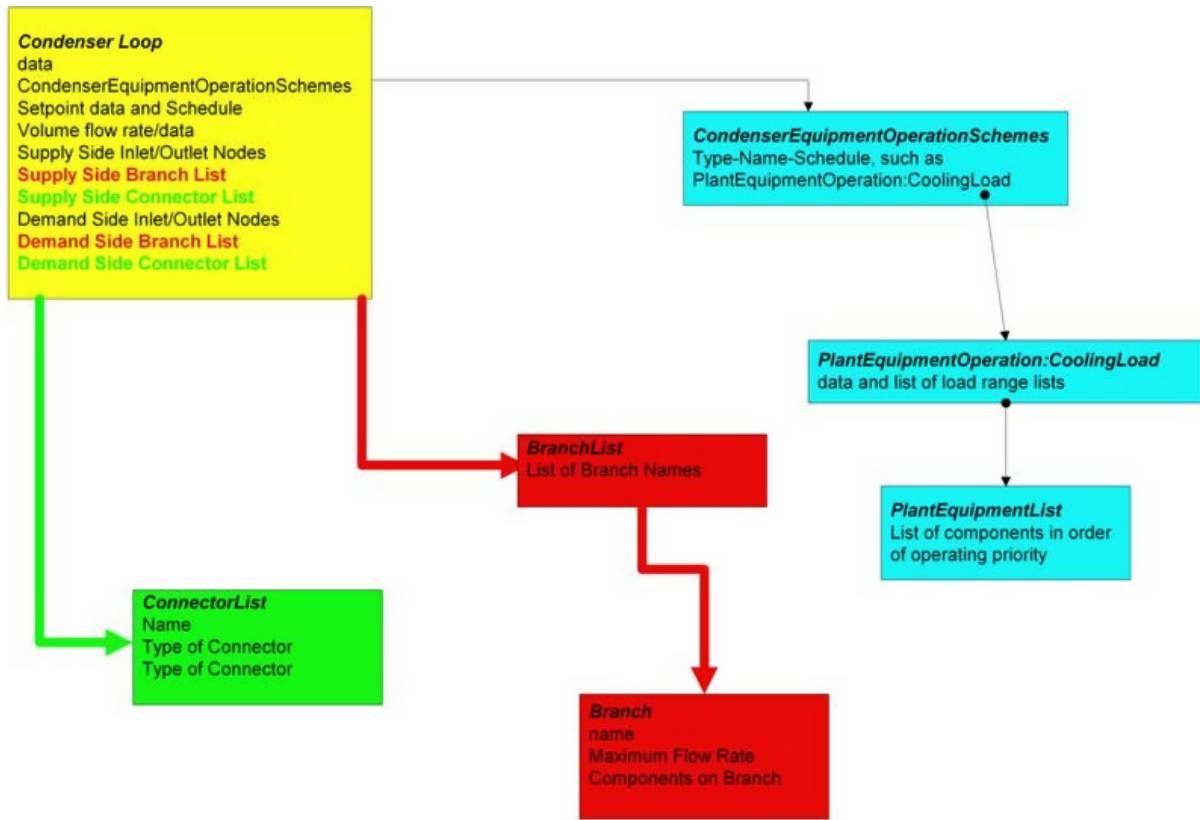

Figure 1.91: Condenser Loop Input Syntax Map

### 1.21.2.1 Inputs

#### 1.21.2.1.1 Field: Name

This alpha field is used as an identifying field for the condenser loop.

#### 1.21.2.1.2 Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Either **Water** or **UserDefinedFluidType** may be used. If the UserDefinedFluidType keyword is used, the following input field i.e. User Defined Fluid Type must have a value (namely the name of a **FluidProperties:GlycolConcentration** object).

#### 1.21.2.1.3 Field: User Defined Fluid Type

This alpha field must be specified when the previous field is set to **UserDefinedFluidType** otherwise it could be left blank. **Water**, **EthyleneGlycol**, and **PropyleneGlycol** are all “built-in” fluids for EnergyPlus (that is, all of the appropriate properties are contained within the program). If the fluid specified here is a mixture of water and ethylene or propylene glycol, then only **FluidProperties:GlycolConcentration** objects need to be specified and the name of the appropriate one is used here. For another water/glycol mixture, a complete set of fluid property data (**FluidProperties:Name** and **FluidProperties:Temperature** objects plus multiple **FluidProperties:Concentration** objects for specific heat, density, etc.) must be specified (Ref dataset: GlycolPropertiesRefData.idf).

#### 1.21.2.1.4 Field: Condenser Equipment Operation Scheme Name

This alpha field is used as an identifying field for the condenser operation scheme. This field ties to the Condenser Operation Schemes input structure, which must also be defined.

#### 1.21.2.1.5 Field: Condenser Loop Temperature Setpoint Node Name

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Condenser Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

#### 1.21.2.1.6 Field: Maximum Loop Temperature

This numeric field contains the maximum allowable temperature in Celsius for this loop.

#### 1.21.2.1.7 Field: Minimum Loop Temperature

This numeric field contains the minimum allowable temperature in Celsius for this loop. This minimum loop temperature is used by the cooling towers to make sure that the minimum is not violated to keep the equipment safe. The minimum is also used to trigger the minimum temperature warning and will notify the user if it gets too low.

#### 1.21.2.1.8 Field: Maximum Loop Flow Rate

This numeric field contains the maximum loop flow rate in cubic meters per second. This field is autosizable.

#### 1.21.2.1.9 Field: Minimum Loop Flow Rate

This numeric field contains the minimum loop flow rate in cubic meters per second.

#### 1.21.2.1.10 Field: Condenser Loop Volume

Volume of the condenser loop in  $m^3$ . This numeric field contains the loop volume for the entire loop, i.e., both the demand side and the supply side. This is used for the loop capacitance calculation. Loop volume ( $m^3$ ) could be calculated from pipe size data but this is not usually known. If zero volume is specified the loop has no fluid heat capacity. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The **autocalculate** option sets the loop volume to the product of the Maximum Loop Flow Rate and the user input for Loop Circulation Time which defaults to 2 minutes (see below). This calculation is described in the Engineering Reference manual.

#### 1.21.2.1.11 Field: Condenser Side Inlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Inlet Node. This node is the inlet to the supply side of the loop.

#### 1.21.2.1.12 Field: Condenser Side Outlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Outlet Node. This node is the outlet of the supply side of the loop.

#### 1.21.2.1.13 Field: Condenser Side Branch List Name

This required alpha field contains the identifying name given to the Condenser Side Branch List. The list referenced here should list all the branches on the supply side of the loop.

#### 1.21.2.1.14 Field: Condenser Side Connector List Name

This required alpha field contains the identifying name given to the Condenser Side Connector List. The list referenced here should list the splitter and mixer on the supply side of the loop.

#### 1.21.2.1.15 Field: Demand Side Inlet Node Name

This required alpha field contains the identifying name given to the Demand Side Inlet Node. This node is the inlet to the demand side of the loop.

#### 1.21.2.1.16 Field: Demand Side Outlet Nodes Name

This required alpha field contains the identifying name given to the Demand Side Outlet Node. This node is the outlet of the demand side of the loop.

#### 1.21.2.1.17 Field: Condenser Demand Side Branch List Name

This required alpha field contains the identifying name given to the Demand Side Branch List. The list referenced here should list all the branches on the demand side of the loop.

#### 1.21.2.1.18 Field: Condenser Demand Side Connector List Name

This required alpha field contains the identifying name given to the Demand Side Connector List. The list referenced here should list the splitter and mixer on the demand side of the loop.

#### 1.21.2.1.19 Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **SequentialLoad** loads each piece of equipment sequentially in the order specified in the **PlantEquipmentList** to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. **SequentialUniformPLR** loads all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the **PlantEquipmentList** until each component is fully loaded, at which point the next subsequent component is added and the load is distributed uniformly based on PLR between the components. **UniformPLR** will load all equipment on the **PlantEquipmentList** to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the **PlantEquipmentList** operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

#### 1.21.2.1.20 Field: Pressure Simulation Type

This field lets user to choose if this plant loop will be involved in a pressure drop calculation. This requires that at least one branch on the loop have pressure drop data. If not, an error will be thrown due to the input mismatch. Currently there are two pressure drop simulation types: “PumpPowerCorrection” and “LoopFlowCorrection”. In both of these methods, branch pressure drop data is used to calculate a dynamic loop pressure drop and is used to update pumping power accordingly. The flow correction method allows the user to enter information regarding the pressure curve of a constant speed pump so that

the simulation can dynamically resolve the pressure vs. flow relationship in the plant loop. This is limited to constant speed pumps, as the variable speed pumps are expected to resolve as if it were controlled by a variable drive, so that they can inherently meet any pressure and flow demand required by the loop. This is also limited to “loop pumps”, where there is a single pump on the plant loop. Common pipe simulations and “branch pump” simulations are not compatible with this level of pressure simulation. See the documentation for the [Pump:ConstantSpeed](#) in order to determine required inputs for this pressure simulation method to be performed. In the pressure drop system, parallel flow rates are not resolved (to match the pressure drop for the parallel system). Enhancements to this calculation are planned which will allow parallel branch flow resolution. See the Engineering Reference document for more information on how this works.

#### 1.21.2.1.21 Field: Loop Circulation Time

This field specifies the time it takes the fluid to circulate through the entire loop. It is only used when Condenser Loop Volume is set to autocalculate. The default is 2 minutes.

An example of this statement used in an IDF is:

```

CondenserLoop,
    Condenser Water Loop,      !- Name
    Water,                    !- Fluid Type

### 1.21.2.2 Outputs

- HVAC,Average,Plant Supply Side Cooling Demand Rate [W]
- HVAC,Average,Plant Supply Side Heating Demand Rate [W]
- HVAC,Average,Plant Supply Side Inlet Mass Flow Rate [kg/s]
- HVAC,Average,Plant Supply Side Inlet Temperature [C]
- HVAC,Average,Plant Supply Side Outlet Temperature [C]
- HVAC,Average,Cond Loop Demand Not Distributed [W]
- HVAC,Average,Plant Supply Side Unmet Demand Rate [W]
- HVAC,Average,Plant Demand Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Supply Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Loop Pressure Difference [Pa]

#### 1.21.2.2.1 Plant Supply Side Cooling Demand Rate [W]

This is the value of the net demand required to meet the cooling setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Cooling Demand Rate will equal sum of the total cooling demand from the demand side components on the loop (typically condenser coils of chillers, etc.). It will also equal the cooling output of all condensing equipment such as cooling towers on the loop less any pump heat added to the fluid. For example, for a condenser loop with one tower and one pump serving one chiller, Plant Supply Side Cooling Demand Rate will equal the tower water-side heat transfer less the pump heat to fluid, and it will also equal the chiller condenser heat transfer rate.

If the condenser loop setpoint is not met, Plant Supply Side Cooling Demand Rate will equal the sum of the total cooling demand from the demand side components on the loop plus the additional cooling required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Cooling Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### 1.21.2.2.2 Plant Supply Side Heating Demand Rate [W]

This is the value of the net demand required to meet the heating setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Heating Demand Rate will equal sum of the total heating demand from the demand side components on the loop. It will also equal the heating output of all heating equipment on the supply side of the loop plus any pump heat added to the fluid. For example, for a condenser loop with one ground loop heat exchanger and one pump serving one water-to-water heat pump, Plant Supply Side Heating Demand Rate will equal the ground loop heat transfer plus the pump heat to fluid, and it will also equal the heat pump condenser side heat transfer rate.

If the condenser loop setpoint is not met, Plant Supply Side Heating Demand Rate will equal the sum of the total heating demand from the demand side components on the loop plus the additional heating required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the

demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Heating Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### **1.21.2.2.3 Plant Supply Side Inlet Mass Flow Rate [kg/s]**

This is the value of the mass flow rate at the Inlet to Condenser Loop on the supply side. There is not an associated Condenser Loop outlet node flow rate since continuity must be maintained in the loop and the outlet must be the same.

#### **1.21.2.2.4 Plant Supply Side Inlet Temperature [C]**

This is the value of the temperature at the Inlet to the condenser loop on the supply side.

#### **1.21.2.2.5 Cond Loop OutletNode Temperature [C]**

This is the value of the temperature at the outlet to the condenser loop on the supply side.

#### **1.21.2.2.6 Cond Loop Demand Not Distributed [W]**

This is the value of the demand that could not be distributed to the condenser equipment because of some constraint in the operation scheme. This is a record of the loop operation scheme supervisory controls after attempting to distribute the load. For example it would be non-zero in situations where the load is larger than the upper limit of capacities set for the condenser equipment controls. This output is for *before* the equipment has actually been simulated whereas the separate output Plant Supply Side Unmet Demand Rate is for *after* the equipment has simulated.

#### **1.21.2.2.7 Plant Supply Side Unmet Demand Rate [W]**

This is the value of the demand NOT provided by the condenser equipment to meet the heating or cooling setpoint of the loop. The value is positive when the condenser equipment cannot meet the setpoint, and the value is negative when the condenser equipment provides more than enough heating or cooling to meet the setpoint. A negative value can happen when the amount of demand is smaller than the minimum capacity of the equipment using the minimum part load ratio.

#### **1.21.2.2.8 Plant Demand Side Loop Pressure Difference [Pa]**

This field is the demand side pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the plant/condenser loop. This particular output is only relevant if the user puts that curve on the demand side of the loop.

#### **1.21.2.2.9 Plant Supply Side Loop Pressure Difference [Pa]**

This field is the supply side pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the plant/condenser loop. This particular output is only relevant if the user puts that curve on the supply side of the loop.

#### **1.21.2.2.10 Plant Loop Pressure Difference [Pa]**

This field is the total pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the

plant/condenser loop. This particular output is relevant regardless of the location of pressure drop curves: demand side, supply side, or both.

## 1.22 Group – Plant-Condenser Control

### 1.22.1 Operation Schemes (Plant and Condenser)

Plants and condenser loops must have some mechanism for controlling the operation of the loop and which equipment is available under what conditions. Since there may be multiple control schemes that are assigned various priorities associated with each loop, an overall operation scheme must be defined. The overall scheme consists of the object name, an identifying name that is referenced in the main plant or condenser loop statement, and a list of operation schemes. Each operation scheme must have the type of operation scheme, its identifying name, and the schedule that defines its availability. Note that the order in which the individual operation schemes appear in this list defines its priority versus the others with the same scheduled availability. The first scheme appearing in the list is given the highest priority, the second scheme has second highest priority, etc. In other words, if according to its schedule, the first operation scheme is available, then it is used by the simulation to define how the plant or condenser loop operates. If it is not available, the second operation scheme in the list is checked to see if it is available until the highest priority scheme that is also available is found. To allow for simultaneous heating and cooling, there is one configuration where multiple operation schemes are available at a given timestep. This is allowed if a user inputs both a heating range based operation and a cooling range based operation with overlapping schedules. The simulation will look at the current loop demand to determine if the cooling scheme should be used or the heating scheme. In other cases, if two schemes overlap (are available at the same time), a fatal error will be encountered.

### 1.22.2 PlantEquipmentOperationSchemes

#### 1.22.2.1 Inputs

##### 1.22.2.1.1 Field: Name

This alpha field contains the identifying name given to the Plant Operation Scheme. This name is placed in the Plant Loop object to select this scheme.

##### 1.22.2.1.2 Field Set: (Component Object Type, Name, Schedule) up to 8

Operation schemes are listed in “priority” order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is “Scheduled” on. That is, if control scheme 1 is not “on” and control scheme 2 is – then control scheme 2 is selected. Only plant equipment should be listed on a Control Scheme for this item.

##### 1.22.2.1.3 Field: Control Scheme <#> Object Type

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:ComponentSetpoint

- PlantEquipmentOperation:ThermalEnergyStorage
- PlantEquipmentOperation:UserDefined

#### 1.22.2.1.4 Field: Control Scheme <#> Name

This alpha field contains the identifying name given to the control scheme. These must be the named versions of the referenced Control Scheme (e.g.. a Uncontrolled Loop Operation with this name or a Cooling or Heating Load Range Based Operation with this name).

#### 1.22.2.1.5 Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing “0 or 1” for each hour of the day. This binary schedule (0 for off, 1 for on) determines if the control scheme is operating for that hour of day or not.

Examples of this statement in two different IDFs:

```
PlantEquipmentOperationSchemes,
    CW Loop Operation,      !- Name
    PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type
    Peak Operation,         !- Control Scheme 1 Name
    On Peak,                !- Control Scheme 1 Schedule
    PlantEquipmentOperation:CoolingLoad, ! Control Scheme 2 Object Type
    Off Peak Operation,     !- Control Scheme 2 Name
    Off Peak;              !- Control Scheme 2 Schedule

PlantEquipmentOperationSchemes,
    CW Loop Operation,      !- Name
    PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type
    Central Chiller Only,   !- Control Scheme 1 Name
    PlantOnSched;           !- Control Scheme 1 Schedule
```

In the first IDF example, “PlantEquipmentOperation:CoolingLoad” is the type of control scheme. “Peak Operation” and “Off Peak Operation” are the names of two different load range based controls defined separately (see below – ). “On Peak” and “Off Peak” are schedules defined elsewhere in the input file.

The load range based operation scheme has two statements associated with it: a main statement that defines the ranges that individual priority settings are valid and the lists of equipment that may be used for each range.

### 1.22.3 CondenserEquipmentOperationSchemes

#### 1.22.3.1 Inputs

##### 1.22.3.1.1 Field: Name

This alpha field contains the identifying name given to the Condenser Operation Scheme.

##### 1.22.3.1.2 Field Set: (Component Object Type, Name, Schedule) up to 8

Operation schemes are listed in “priority” order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is “Scheduled” on. That is, if control scheme 1 is not “on” and control scheme 2 is – then control scheme 2 is selected. Only condenser equipment should be listed on a Control Scheme for this item.

### 1.22.3.1.3 Field: Control Scheme <#> Object Type

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

This alpha field contains the keyword for the type of control scheme used. Currently, the available options are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:OutdoorDryBulb
- PlantEquipmentOperation:OutdoorWetBulb
- PlantEquipmentOperation:OutdoorDewpoint
- PlantEquipmentOperation:OutdoorRelativeHumidity
- PlantEquipmentOperation:OutdoorDryBulbDifference
- PlantEquipmentOperation:OutdoorWetBulbDifference
- PlantEquipmentOperation:OutdoorDewpointDifference
- PlantEquipmentOperation:UserDefined

The condenser operation schemes apply to the equipment on the ‘supply side’ of the condenser loop—pumps, cooling towers, ground coupled heat exchangers, etc. The keywords select the algorithm that will be used to determine which equipment is available for each timestep. The Load Schemes schemes select a user specified set of equipment for each user specified range of a particular simulation variable. Load schemes compare the demand on the condenser supply side with specified load ranges and associated equipment lists. Outdoor schemes compare the current value of an environmental parameter with user specified ranges of that parameter.

### 1.22.3.1.4 Field: Control Scheme <#> Name

This alpha field contains the identifying name given to the control scheme.

### 1.22.3.1.5 Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing “0 or 1” for each hour of the day. This binary schedule (0 for off, 1 for on) determines which control scheme is operating for a particular hour. The schedule facilitates daily or seasonal changes in control schemes to meet demand side management or energy conservation goals.

Scheduling conflicts are handled by selecting the first available scheme in order of appearance in the list.

Examples of this statement in two IDFs:

```
CondenserEquipmentOperationSchemes,
    Tower Loop Operation,      !- CondenserOperationSchemeName
    PlantEquipmentOperation:CoolingLoad,  Control Scheme 1 Object Type
    Year Round Tower Operation, !- Control Scheme 1 Name
    PlantOnSched;           !- Control Scheme 1 Schedule

CondenserEquipmentOperationSchemes,Tower Loop Operation,
```

```
PlantEquipmentOperation:CoolingLoad, Peak Load Operation, AFTERNOONSCHEDULE,
PlantEquipmentOperation:CoolingLoad, OffPeak Load Operation, MORNINGSCHEDULE,
PlantEquipmentOperation:OutdoorWetBulb, NightOperation, NIGHTSCHEDULE;
```

Each schedule (AFTERNOONSCHEDULE, MORNINGSCHEDULE, NIGHTSCHEDULE) invokes its associated operation scheme (Peak Load Operation, OffPeak Load Operation, NightOperation). The type of operation scheme and its name references the input syntax associated with the range specification and the associated equipment.

## 1.22.4 PlantEquipmentOperation:Uncontrolled

Uncontrolled loop operation simply specifies a group of equipment that runs ‘uncontrolled’. If the loop runs, this equipment will run also, unless turned off by the loop flow resolver to maintain continuity in the fluid loop.

### 1.22.4.1 Inputs

#### 1.22.4.1.1 Field: Name

This alpha field contains the identifying name for the control scheme.

#### 1.22.4.1.2 Field: Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the Load Range Equipment List input structure, which must also be defined.

#### 1.22.4.1.3 Field: Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the [PlantEquipmentList](#) or [CondenserEquipmentList](#) input structure, which must also be defined.

## 1.22.5 PlantEquipmentOperation:CoolingLoad

### 1.22.5.1 Inputs

## 1.22.6 PlantEquipmentOperation:HeatingLoad

The [PlantEquipmentOperation:CoolingLoad](#) and [PlantEquipmentOperation:HeatingLoad](#) objects define the different ranges and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the [PlantEquipmentList](#) or [CondenserEquipmentList](#) objects).

### 1.22.6.1 Inputs

#### 1.22.6.1.1 Field: Name

This alpha field contains the identifying name for the control scheme.

#### 1.22.6.1.2 Field Set: (Lower limit, Upper Limit, Equip List name) up to 10

#### 1.22.6.1.3 Field: Load Range <#> Lower Limit

This numeric field contains the lower demand range (W) for the equipment list. If demand is below this value, then this equipment list will not turn on to meet the demand.

#### 1.22.6.1.4 Field: Load Range <#> Upper Limit

This numeric field contains the upper demand range (W) for the equipment list. If demand is above this value, then this equipment list will not turn on to meet the demand.

#### 1.22.6.1.5 Field: Range <#> Equipment List Name

This alpha field contains the identifying name for the Equipment List (i.e., the name of a **PlantEquipmentList** or **CondenserEquipmentList** object).

An example of these statements in an IDF is:

```
PlantEquipmentOperation:CoolingLoad, Peak Operation,
    0,7000, Chiller Plant,
    7000,24500, Chiller Plant and Purchased,
    24500,500000, Purchased Only;
```

This particular load based operation scheme (above) has three different ranges. “Chiller Plant”, “Chiller Plant and Purchased”, and “Purchased Only” are names which link to various **PlantEquipmentList** or **CondenserEquipmentList** objects as described below. Gaps may be left in the load ranges specified, but to operate equipment over the entire range the upper limit of a given range must equal the lower limit of the next range as shown in the example. If gaps are left in the load ranges specified, a warning message will be issued when the load to be met falls within a load range “gap”. If the user wishes to leave a load range “gap” for a specific reason (no equipment to operate on this plant [or condenser] loop within this load range) and does not want the warning messages to be generated, then specify a lower limit, upper limit and equipment list name for the gap and do not specify any equipment in the associated equipment list, as shown below.

```
PlantEquipmentOperation:CoolingLoad, Peak Operation,
    0,7000, Chiller Plant,
    7000,7100, NoEquipmentOperationOnThisPlantLoop,
    7100,24500, Chiller Plant and Purchased,
    24500,500000, Purchased Only;

PlantEquipmentList,

### **1.22.7 PlantEquipmentOperation:OutdoorDryBulb**

### **1.22.8 PlantEquipmentOperation:OutdoorWetBulb**

### **1.22.9 PlantEquipmentOperation:OutdoorRelativeHumidity**

### **1.22.10 PlantEquipmentOperation:OutdoorDewpoint**

The outdoor operation objects define the different ranges of the various environmental parameters and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the [CondenserEquipmentList](#)).

The fields for each of these are:

#### **1.22.10.1 Inputs**

##### **1.22.10.1.1 Field: Name**

This alpha field contains the identifying name for the control scheme.

##### **1.22.10.1.2 Field Set: (Lower limit, Upper Limit, Equip List name) up to 10**

##### **1.22.10.1.3 Field: <specific type> Range <#> Lower Limit**

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is below this value, then this equipment list will not turn on to meet the demand.

##### **1.22.10.1.4 Field: <specific type> Range <#> Upper Limit**

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is above this value, then this equipment list will not turn on to meet the demand.

##### **1.22.10.1.5 Field: Range <#> Equipment List Name**

This alpha field contains the identifying name for the Equipment List (i.e., the name of a [CondenserEquipmentList](#) object).

### **1.22.11 PlantEquipmentOperation:OutdoorDryBulbDifference**

#### **1.22.11.1 Inputs**

### **1.22.12 PlantEquipmentOperation:OutdoorWetBulbDifference**

#### **1.22.12.1 Inputs**

### **1.22.13 PlantEquipmentOperation:OutdoorDewpointDifference**

The Delta Temperature based control strategies help to control any condenser equipment based on the difference between a reference node temperature and any environmental temperature. For example a cooling tower can be controlled by a strategy, which looks at the difference between the tower inlet temperature and wet-bulb temperature. A difference range is specified for each equipment list.

### 1.22.13.1 Inputs

#### 1.22.13.1.1 Field: Name

This alpha value contains the identifying name of the control strategy. This name appears as ‘control scheme name’ in Condenser Operation Scheme object.

#### 1.22.13.1.2 Field: Reference Temperature Node Name

This alpha value specifies the reference node for the operation scheme identified in the first field.

#### 1.22.13.1.3 Field Set: (Lower limit, Upper limit, Equipment List)

##### 1.22.13.1.4 Field: <specific type> Range <#> Lower Limit

This numeric field specifies the minimum temperature difference required for the equipment specified in the equipment list to operate.

##### 1.22.13.1.5 Field: <specific type> Range <#> Upper Limit

This numeric field specifies the maximum temperature difference below which the equipment specified in the equipment list is available.

##### 1.22.13.1.6 Field: Range <#> Equipment List Name

This alpha field contains the identifying name for the Equipment List (i.e., the name of a [CondenserEquipmentList](#) object).

## 1.22.14 PlantEquipmentOperation:ComponentSetpoint

In addition to load range based control on the plant loop, sequencing the plant components based on the outlet temperature of individual equipment is allowed. This scheme is common to many present-day Energy Management Systems sequencing. In this scheme, the sequencing is done based on the order specified in the control object described below.

However, when sequencing a boiler and a cooling tower to control the heating and cooling set point temperatures of a condenser loop, it is recommended that the boiler and the cooling tower be placed in a parallel configuration. The series configuration of these two equipment, though possible to model them, may result in simultaneous heating and cooling operation when the boiler is ON and the cooling tower operates in free cooling mode, i.e., the cooling tower may provide free cooling that could over cool the water below the boiler heating setpoint temperature.

### 1.22.14.1 Inputs

#### 1.22.14.1.1 Field: Name

This field specifies the name of the operation scheme.

#### 1.22.14.1.2 Field Set: Equipment Object Type, Name, Demand Calculation Node, Setpoint Node, Flow Rate, Operation Type)

##### 1.22.14.1.3 Field: Equipment <#> Object Type

This field specifies the type of equipment controlled by scheme.

##### 1.22.14.1.4 Field: Equipment <#> Name

This field specifies the name of the controlled equipment.

#### 1.22.14.1.5 Field: Demand Calculation <#> Node Name

The component demand will be calculated using the difference between the temperature at the demand node and the component set point temperature.

#### 1.22.14.1.6 Field: Setpoint <#> Node Name

Each component controlled under temperature based control will have its own set point different from the loop set point. This field specifies component set point node (Generally its outlet temperatures). This node is acted upon by a SetpointManager in order to obtain the setpoint at any simulation timestep.

#### 1.22.14.1.7 Field: Component <#> Flow Rate

This numeric field specifies the design flow rate for the component specified in earlier fields. This flow rate is used to calculate the component demand. The field can be set to autosize, if the user wants the program to calculate the design flow. This would generally be set to autosize when the user does not know the component flow rate and does a sizing calculation for the corresponding component.

#### 1.22.14.1.8 Field: Operation<#> Type

This alpha field specifies the operation mode for the equipment. The equipment can be in any of the three modes viz. Cooling, Heating and Dual. Dual is used when the components both as heating and cooling equipment (for example heat pumps).

And, as an example in an IDF:

```

PlantEquipmentOperationSchemes,
    CW Loop Operation,      !- PlantOperationSchemeName
    PlantEquipmentOperation:ComponentSetpoint, ! Control Scheme 1 Object Type
    Test Scheme,           !- Control Scheme 1 Name
    On;                   !- Control Scheme 1 Schedule

PlantEquipmentOperation:ComponentSetpoint,
    Test Scheme,
    CHILLER:ELECTRIC,     !- Equipment 1 Object Type
    Little Chiller,        !- Equipment 1 Name
    Little Chiller Inlet Node, !- Demand Calculation 1 Node Name
    Little Chiller Outlet Node, !- Setpoint 1 Node Name
    0.0011,                !- Component 1 Flow Rate
    COOLING,               !- Operation 1 Type
    CHILLER:ELECTRIC,     !- Equipment 2 Object Type
    Big Chiller,            !- Equipment 2 Name
    Big Chiller Inlet Node, !- Demand Calculation 2 Node Name
    Big Chiller Outlet Node, !- Setpoint 2 Node Name
    0.0011,                !- Component 2 Flow Rate
    COOLING;               !- Operation 2 Type

```

### 1.22.15 PlantEquipmentOperation:ThermalEnergyStorage

Users of thermal energy storage, particularly ice storage systems, are often faced with a challenge of specifying input for these systems. Essentially, they have to define various setpoint managers, temperature schedules, etc. in order to make the system functional. This plant/condenser control type simplifies the input somewhat by eliminating both a setpoint manager and a schedule for each piece of equipment that makes up the ice storage system. In fact, this operation scheme internally creates the setpoint managers required by the equipment listed as operated by the scheme defined by this syntax. While the more complex definition is possible and provides more flexibility like hourly variation of setpoint temperatures at the outlet of each piece of equipment, this input provides the most convenient method for making the system to work and assumes a single charging setpoint temperature and a single discharging setpoint temperature. For most systems, this is all that is needed.

### 1.22.15.1 Inputs

#### 1.22.15.1.1 Field: Name

This field defines the name of the thermal energy (ice) storage plant equipment operation scheme that will be referenced by the [PlantEquipmentOperationSchemes](#) list in the plant input.

#### 1.22.15.1.2 Field: On-Peak Schedule

This field defines the name of an integer schedule that determines when on-peak electric pricing is in effect. This value is used to determine whether or not the ice storage system should be charging the ice storage unit. In the schedule, a value of 1 (or greater) corresponds to being in the on-peak period while any value of 0 or less corresponds to being in the off-peak period.

#### 1.22.15.1.3 Field: Charging Availability Schedule

This field defines the name of an integer schedule that determines whether or not the system may enter charging mode off-peak. If the current value of the on-peak schedule is “off”, then charging can take place if the charging availability schedule is “on”. If the on-peak schedule is “off” and charging availability is “off”, then charging is not allowed and the chiller and ice storage units controlled by this statement are operating to meet the non-charging chilled water temperature defined by the next input parameter. In this schedule, a value of 1 (or greater) corresponds to “on” when charging is available during an off-peak period while any value of 0 or less corresponds to chillers not being allowed to charge even during off-peak.

#### 1.22.15.1.4 Field: Non-Charging Chilled Water Temperature
